WD-PZ19C	TDS (calculated)	5,829	mg/L	REG	2/20/2013

[1] Groundwater samples for cations and anions collected on different dates due to low yield.

Total dissolved solids calculated from sum of major ions (calcium, magnesium, sodium, potassium, carbonate, bicarbonate, sulfate, and chloride)

REG = regular sample

FD = field duplicate

FR = field replicate

Table A.8. PORTS Groundwater Data Summary

Station	Chemical	Min Detected Result	Max Detected Result	Units	Total Number of Detects	Total Number of Analyses
WD-MW01B	1,2-Dimethylbenzene	3.30E-01	3.60E-01	ug/L	3	11

Notes:
State Plane coordinates are NAD 1983 State Plane Ohio South FIPS 3402 (ft).

AMSL = above mean sea level
FIPS = Federal Information Processing Standards
NA = not available
NAD = North American Datum
OSDC = on-site disposal cell

Notes:
State Plane coordinates are NAD 1983 State Plane Ohio South FIPS 3402 (ft).
Datum in italics is the initial open-borehole datum elevation (prior to conversion to 10-ft screened piezometer).

FIPS = Federal Information Processing Standards
AMSL = above mean sea level
NAD = North American Datum
OSDC = on-site disposal cell

SITE **Portsmouth Gaseous Diffusion Plant** **Piketon, Ohio**	PROJECT **Fluor B&W Portsmouth-OSDC Lab Testing**

DESCRIPTION

20.5 — 741.3

SHALE, laminated, medium gray, soft

-oxidized zones at 20.8', 23.5'
-vertical fracture at 21'
-fractures at 21.3', 21.7' 30° horizontal and vertical, 21.8' 20° with oxidized zone

24.4 — 737.4

25 — 736.8 **SHALE**, highly weathered, yellowish-brown, soft

25.5 — 736.3 **SANDSTONE**, moderate reddish-brown to moderate yellow, hard

-10° fractures at 25', 25.1', and 25.2'

26 — 735.8 **SHALE**, indurated clay, highly weathered, laminated, yellowish-brown, soft

SHALE, laminated, dark gray, soft, with interbedded sandstone 44.1' to 63.2', thinly bedded to cross bedded, gray, hard
-vertical fracture at 26.3' and 43.2'
-45° fracture with iron stain at 26.5' and 28.7'

GEOPHYSICAL WELL LOGGING REPORT

Prepared for: Flour-B&W Portsmouth LLC
TOR No.: TOR007
Contract No.: PO-0000059

December 16, 2011

Subject: Geophysical Well Logging Results of WD-PZ-08C through WD-PZ-14C in
Study Area D
Portsmouth Gaseous Diffusion Plant
Piketon, Ohio

Advanced Geological Services (AGS) presents this submittal to Flour-B&W Portsmouth LLC (FBP) summarizing the geophysical well logging investigation completed by AGS on November 28 through November 30, 2011 at the Portsmouth Gaseous Diffusion Plant (PORTS) located in Piketon, Ohio. This work was completed in support of the Portsmouth Decontamination and Decommissioning Project.

Seven piezometers were geophysically logged with multiple wireline tools to characterize the bedrock and the degree of fracturing within the bedrock. All seven of the piezometers were located in Study Area D. The piezometers were six inches in diameter, had total depths of between 43 feet and 117 feet.

LOCAL GEOLOGY

The bedrock encountered in the study area is part of the Waverly Group, of Mississippi age (Young, et al., 1996). The formations present at the locations of the piezometers included, from oldest to youngest, the Berea Formation, the Sunbury Formation and the Cuyahoga Formation. All of the piezometers logged were completed in the Cuyahoga Formation, which is the uppermost bedrock unit in the study area. The Cuyahoga Formation is a composed of shale and sandstone beds. Regionally, bedrock at dips towards the southeast at an angle of less than 0.5^o (25 to 30 feet per mile) (Young, et al., 1996).

1.0 METHODOLOGY

A suite of geophysical logs was completed in each of the piezometers. Standard geophysical logs and borehole image logs were collected to provide detailed information about the bedrock at each piezometer.

The logs that were collected for this investigation include:

- 3-arm Caliper
- Natural Gamma
- Single-point Resistance
- Normal Resistivity (16-inch & 64-inch)
- 40-inch Lateral Resistivity (calculated)
- Digital Acoustic Televiewer (ATV)

All logs, except the ATV logs were acquired using a Compu-Log Portable Logging System manufactured by Century Geophysical Corporation. The ATV logs were acquired with a Mount Sopris Matrix logging system.

1.1. CALIPER LOGS

The caliper log measures variations in borehole size as a function of depth in a well. The log data enables (a) the detection of competent or fractured geologic units, (b) the location of washouts or tight zones, (c) the optimal placement of well screen, sand, and bentonite, and (d) the establishment of appropriate borehole correction factors to be applied to other well log curves. Further, when run in combination with other logs, the caliper log may be an indicator of lithologic makeup and degree of consolidation. The typical caliper response in a fractured, or weathered, unit is a relatively abrupt increase in borehole size.

1.2. NATURAL GAMMA RAY LOGS

The natural gamma ray log is a passive instrument that measures the amount of naturally occurring radioactivity from geologic units within the borehole. Common naturally occurring radioelements include potassium, thorium, and uranium. Potassium and thorium are often the most common in fine-grained rock sequences. The gamma ray log is an excellent lithologic indicator because fine-grained clays and shales contain a higher radioelement concentration than limestones or sands. Gamma ray values are often used to assess the percentage of clay materials (indurated or non-indurated) that are present within a formation by utilizing empirically derived equations and sand-shale base line information.

The natural radioactivity range for earth materials is as follows:

Shales Clays Marls
Silts Sand
(sandstone)
Limestone Dolomite

Radioactivity
Increase

1.3. SINGLE-POINT RESISTANCE LOGS

Single-point resistance measurements are made by passing a constant current between two electrodes and recording the voltage fluctuations as the probe is moved up the hole. The resistance variations measured in the borehole are primarily caused by variations in the immediate vicinity of the downhole electrode.

The resistance log is strongly affected by the resistance of the drilling fluid and variations in borehole diameter. It is extremely useful for detecting fractures in boreholes with relatively constant diameter. In sedimentary environments, the resistance log generally follows the variations in resistivity of the formation. Shales generally exhibit low values, sandstones have intermediate values, while coal and limestone beds have high resistance values.

1.4. ELECTRICAL RESISTIVITY LOGS

Resistivity is a measure of how well an electric current passes through a material. Formation resistivity is an intrinsic property of rocks and depends on the porosity and resistivity of the interstitial fluid and rock matrix.

In sedimentary rocks, the resistivity values of shales is generally lower than the resistivity of sandstone, which is lower than the resistivity of limestone. The resistivity log often shows a picture of the overall depositional sequence in sedimentary environment. Resistivity of unweathered igneous and metamorphic rocks are often extremely high when compared to resistivity in sedimentary rocks, with values that are commonly thousands of ohm-meters.

2.0.1 16-Inch and 64-Inch Normal Resistivity Logs

The normal resistivity logs are generated by non-focused current resistivity instrumentation within the well bore. The ultimate objective of these measurements is to determine the true resistivity of the formation (matrix and fluids). The normal electrode configuration assumes a point source of current from which the voltage drop is measured by a potential electrode in the well. A second set of current and potential electrodes are positioned at a large distance (ground surface) from the downhole electrodes to complete the circuit. The distance between the downhole current electrode and the downhole voltage electrode is either 16 inches or 64 inches. The volume of material measured is approximately two times the electrode separation: 32 inches and 128 inches, respectively. The calculation of resistivity is determined by applying Ohm's Law and known electrode separations.

Since the 64-inch normal utilizes a greater electrode separation, the instrument will measure more deeply into the formation and obtain resistivity values that closely approximate the true formation resistivity. Conversely, the 16-inch normal device will record resistivities that are found in a zone that is at least partially invaded by borehole fluids. In the case where borehole mud pressures are greater than formation water pressures, a comparison of these curves gives an indication of the depth of invasion of borehole fluids and formation permeability. If formation pressures are greater, the true resistivity values are easier to attain due to the lack of influence of the borehole fluids.

2.0.2 40-Inch Lateral logs

Lateral resistivity logs are designed to measure resistivity beyond the invaded zone by use of a long electrode separation. The 40-inch lateral log provided in this report is a log calculated by the logging software provided by the logging system manufacturer (Century Geophysical Corporation). It is computed from the 16-inch normal and 64-inch normal readings. The curve is generated through the relation, L40 = (N16*4 - N64)/3, where L40 is the 40-inch lateral value, N16 is the measured 16-inch normal resistivity reading, and N64 is the 64-inch normal resistivity reading.

1.5. ACOUSTIC TELEVIEWER (ATV) LOGS

The acoustic televiewer log provides an oriented high-resolution image of the borehole using high-resolution sound waves. The oriented image of the borehole can be presented in both amplitude and travel time. Results from this tool provide location and orientation information of features such as fractures, lithologic contacts and cavities, as well as relative smoothness of the sidewalls of the well bore. The relative smoothness of the well bore sidewalls can be used qualitatively in conjunction with other logs to assist with characterizing the bedrock lithology, or degree of weathering. The ATV digitizes up to 244 measurements around the borehole every 0.02 feet along the length of the borehole. Since the acquired image is digitized and properly oriented with respect to borehole deviation and tool rotation, it allows data processing to provide accurate strike and dip information of structural features.

2.0 RESULTS AND DISCUSSION

Piezometers WD-PZ-08C, WD-PZ-09C, WD-PZ-10C, WD-PZ-11C, WD-PZ-12C, WD-PZ-13C, and WD-PZ-14C were logged during this investigation. All piezometers were 6-inch diameter, and had steel casing. Prior to logging, the water levels in the piezometers were generally below the bottom of the steel casing. The resistance, resistivity and ATV logs all require a water filled borehole to provide meaningful results. Therefore, each of the piezometers was filled to the top with fresh water immediately prior to the start of logging.

The bedrock encountered in each of the piezometers was predominantly fine-grained, thinly bedded shale, with occasional thin sandstone layers. The sandstone, when present, was most commonly less than 2 to 3 inches inches thick, although some sandstone layers were up to approximately 1.8 feet thick. The geophysical logs suggest that the shale is thinly laminated and friable.

Overall, the quality of the geophysical logs was very good. The geophysical logs are provided as an attachment at the end of this report. Variations in the resistance, resistivity and natural gamma logs, in conjunction with the caliper and ATV responses allow identification of lithologic changes encountered within the piezometers. Generally a sandstone unit will produce a lower natural gamma response, and a higher resistance and resistivity response than a shale. Shales also tend to be softer than sandstones, which results in a slight widening of the borehole during drilling, that can be detected with the caliper tool.

The ATV logs can also be used to distinguish between shale and sandstone units. Generally, the thinly bedded, friable shale encountered in the piezometers produced a rough image that appears static filled. This character is caused by the rough sidewalls of the friable shale in the well bore that scatters the acoustic signal. On the other hand, the acoustic image produced by a sandstone bed is cleaner, and relatively free of the static because of the smoother sidewalls of the well bore.

Logs from WD-PZ-13C provide a good example of the sandstone versus shale response in the geophysical logs. The sandstone layer from a depth of 30.7 feet to 32.5 feet produces a decrease in the natural gamma response, an increase in the resistance and resistivity responses, a decrease in borehole diameter shown in the caliper log, and a clear, static free ATV response. This particular sandstone layer was thicker than most encountered during this investigation, but similar responses can also be seen in the thinner sandstone layers encountered.

The geophysical logs also indicate that the bedrock in the investigation area is free from any major bedding plane fractures, joints, or faults. Bedrock fractures are often observed in the caliper log as an abrupt widening of the borehole diameter. ATV logs also provide high-resolution of the borehole images that allow clear identification of bedding plane fractures, joints, and faults. If partings in the bedrock are very tight, do not cause a widening of the borehole, or have no acoustic response, then no fractures are observed.

The plotted range of the borehole diameter of the caliper logs is very small, from a diameter of 6 inches to 7 inches (see attached logs). This narrow range was used to accentuate changes in the borehole diameters that do occur. Commonly a significant bedrock fracture will produce a widening of the borehole that is abrupt, and often increases the borehole diameter by 1 inch or more. At this site, the caliper responses only show variations in borehole diameter of up to several tenths of an inch, which is considered very small. Most often the changes in borehole diameter observed at this site are related to changes in lithology, not the presence of fractures.

Bedrock fractures in ATV logs are identifiable as a dark, continuous line that has a sinusoidal shape if the fracture is dipping, or as a straight, continuous, horizontal line if the fracture is perfectly flat. Probably the best example of a fracture from the logs collected during the current investigation occurs in WD-PZ-13C, at a depth of 30.7 feet. This is a bedding plane fracture that is located at the upper contact of a sandstone layer, and at the base of a shale. Although this is an identifiable bedding plane fracture, it would not be considered a major fracture.

As mentioned previously, the geophysical well logs are provided as an attachment to this report. Depths of all the logs are relative to the ground surface. Results and interpretations from the geophysical logs of each of the piezometers will be briefly described and discussed below.

2.1 WD-PZ-08C

Piezometer WD-PZ-08C was cased to a depth of 29 feet, and had a total depth of approximately 47 feet. A layer of sediment had settled in the bottom of the piezometer making it difficult to provide an accurate total depth.

From the bottom of casing to a depth of 45.5 feet the piezometer penetrates relatively homogeneous shale. Based on the ATV response, the shale beds are thinly laminated and likely readily friable. No distinctive bedding planes, fractures, or joints are noted in this portion of the piezometer.

A sandstone bed is encountered at a depth of 45.5 feet. A bedding plane fracture is present at the upper contact of this sandstone, and can be seen in the ATV log. There is no discernible response to the bedding plane fracture in the caliper log suggesting that this fracture is tight, and may have limited hydraulic conductivity.

It is not possible to see the bottom of the sandstone layer in the ATV log because of the accumulated sediments in the bottom of the piezometer. Based on the resistance and natural gamma responses, the sandstone layer probably extends to the bottom of the piezometer.

2.2 WD-PZ-09C

Piezometer WD-PZ-09C was cased to a depth of 30.4 feet and had a total depth of approximately 117 feet. Sediment accumulation in the bottom of the piezometer made it difficult to accurately determine the total depth.

The piezometer penetrated shale with occasional thin sandstone layers or stringers throughout its length. The most prominent sandstone layers were encountered at the depth intervals of 34.8-35.3, 37.1-37.8, 38.2-38.8, 78.8-80.4, and 82.3-82.9 feet. A number of thinner sandstone stringers are interspersed throughout the piezometer. Based on the ATV response, the sandstone stringers are more numerous between the bottom of casing and a depth of 83 feet. Below 83 feet, the sandstone stringers become fewer or more widely spaced.

No fractures or joints were noted from the geophysical log responses. It appears that bedding plane contacts are tight and not noticeably weathered or fractured.

2.3 WD-PZ-10C

Piezometer WD-PZ-10C was case to a depth of 23 feet, and has a total depth of approximately 41.5 feet. As with the other piezometers, sediment accumulation in the bottom of the piezometer makes it difficult to determine an accurate total depth.

Only 18.5 feet of open hole was available for logging at this location. The uncased portion of the piezometer penetrated homogeneous, thinly bedded shale throughout its length. No sandstone layers were noted in this piezometer. No bedding fractures, or joints were identified from the geophysical logs.

2.4 WD-PZ-11C

Piezometer WD-PZ-11C was cased to a depth of 30 feet and had an approximate total depth of 70 feet. Sediments accumulated in the bottom of the piezometer made it difficult to accurately determine the bottom of the piezometer.

The lithology of this piezometer from the bottom of casing to 67.3 feet is predominantly shale with occasional thin stringers of sandstone. Based on the ATV response, a sandstone layer may be present at the depth 67.3 feet. It is difficult to determine the presence of a sandstone layer at this depth because of the presence of the sediments accumulated at the bottom of the piezometer. The very close proximity of the well bottom also makes it hard to evaluated the natural gamma, resistance and resistivity curves. No bedding plane fractures, or joints were noted in the geophysical logs.

An item of note is a slight shift in the resistance and resistivity responses at a depth of 56 feet, along with a subtle change in the character of the ATV log. These changes may be caused by the natural water level in the piezometer, or by a sudden increase in the amount of suspended sediment in the water column. If these changes are caused by the presence of the natural water table, then the pore space of the bedrock below 56 feet is water saturated, and may have a slight weathering alteration, while above 56 feet, the pore space of the bedrock is partially saturated, or unsaturated.

2.5 WD-PZ-12C

Piezometer WD-PZ-12C was cased to a depth of 29 feet and has a total depth of approximately 73 feet. Similar to the other piezometers, sediments accumulated in the bottom of the piezometer makes accurate total depth determinations difficult. WD-PZ-12C penetrates shale with occasional thin sandstone stringers throughout its length. The sandstone stringers are most common between the bottom of casing and 36 feet. The stringers are less numerous, and/or less common, below a depth of 36 feet. No bedding plane fractures, or joints were noted in the geophysical logs.

A shift in the resistance and resistivity responses, along with a change in the character of the ATV log was noted at a depth of 63.5. These responses were more pronounced, but similar to those noted in WD-PZ-11C at a depth of 56 feet. Unlike WD-PZ-11C, the caliper log from WD-PZ-12C shows a slight widening of the borehole. The slight widening of the borehole, along with the other changes noted, would suggest that the changes are more likely related to the level of the natural water table rather than suspended sediments in the water column. The combined logs would indicate that there may be a slight weathering of the shale at the top of the water table, or in the vadose zone.

2.6 WD-PZ-13C

Casing in WD-PZ-13C extended to a depth of 15.2 feet, and the total depth was approximately 69 feet. Sediment accumulation in the bottom of the piezometer makes accurate total depth determination difficult.

The bed rock from the bottom of casing to a depth of 30.8 feet is shale that may be friable, or partially weathered. A prominent sandstone layer is present between 30.8 and 32.5 feet. From the base of the sandstone to the bottom of the piezometer, the bedrock is composed of shale with occasional sandstone stringers.

A bedding plane fracture is present at the shale-sandstone contact at a depth of 30.8 feet. This fracture does exhibit both a caliper response and an ATV response. This was the most prominent fracture identified during this investigation, but still would not be considered a major fracture. No additional fractures of joints were identified within this piezometer.

2.7 WD-PZ-14C

Piezometer WD-PZ-14C was cased to a depth of 10.6 feet, and had a total depth of approximately 46 feet, although accumulated sediments in the bottom of the piezometer made total depth determination difficult. A sandstone layer was present from the bottom of casing to a depth of 13 feet. Shale was present from the base of the sandstone at 13 feet, to the bottom of the piezometer. The shale is likely friable or slightly weathered based upon the caliper and ATV responses. There appeared to be a thicker accumulation of sediments in the bottom of this piezometer than in most of the others, which could suggest that the shale is softer, or more weathered than in other piezometers.

No bedding plane fractures, or joints were noted in the geophysical logs.

3.0 SUMMARY AND CLOSING

Geophysical well logs were completed in seven piezometers located in Study Area D. Piezometers logged included WD-PZ-08C through WD-PZ-14C. Total depths of the piezometers varied between 43 and 117 feet. The predominant lithology encountered was a fine grained, thinly bedded, friable shale. Piezometer WD-PZ-10C was shale throughout. Piezometer WD-PZ-08 penetrated shale, and terminated in a sandstone layer at the bottom. Piezometer WD-PZ-14C had a single layer of sandstone immediately at the bottom of casing, then was shale through the remainder of the piezometer. Piezometers WD-PZ-09C, WD-PZ-11C, WD-PZ-12C, and WD-PZ-13C all were composed of shale with occasional sandstone stringers, with piezometers WD-PZ-09C and WD-PZ-13C also having several thicker sandstone layers.

Bedding plane fractures were noted at upper contact of sandstone layers in WD-PZ-08C, and WD-PZ-13C. Neither of the bedding plane fractures identified would be considered a major fracture based on the caliper and ATV responses. No additional bedding plane fractures or joints were identified in the geophysical logs. The shale bedrock may be friable and easily broken, but no major cross-cutting planar structures were noted in the logs.

The data collection and interpretation methodologies used in this investigation are consistent with standard practices applied to similar geophysical investigations. The correlation of geophysical responses with probable subsurface features is based on the past results of similar surveys although it is possible that some variation could exist at this site.

GEOPHYSICAL WELL LOGGING REPORT

Prepared for: Flour-B&W Portsmouth LLC
TOR No.: TOR011
Contract No.: PO-0004760
Document: 004760-004-TOR011 Rev. 0

May 31, 2013

Subject: Geophysical Well Logging Results of WD-PZ-09, WD-PZ-12C, WD-PZ-15C, WD-PZ-18C, WD-PZ-20C, and WD-SB-40 in Study Area D
Portsmouth Gaseous Diffusion Plant
Piketon, Ohio

Advanced Geological Services (AGS) presents this submittal to Flour-B&W Portsmouth LLC (FBP) summarizing the geophysical well logging investigation completed by AGS on April 22 through April 25, 2013 at the Portsmouth Gaseous Diffusion Plant (PORTS) located in Piketon, Ohio. This work was completed in support of the Portsmouth Decontamination and Decommissioning Project.

Borehole image logs, that included an acoustic televiewer (ATV) log, an optical televiewer (OPTV) log and a borehole video were completed in several boreholes. The logs were completed to assist with determining the degree of fracturing present within the bedrock. Boreholes logged with ATV, OPTV, and borehole video included, WD-PZ-09C, WD-PZ-12C, WD-PZ-15C, WD-PZ-18C, and SB-40.

One additional borehole, WD-PZ-20C, was logged with OPTV, and the bottom portion, below the standing water level, was logged with ATV. The logs in WD-PZ-20C were completed to determine if any significant bedrock fractures were present in the bottom several feet of the borehole that could effect the ability to place grout in the borehole.

LOCAL GEOLOGY

The bedrock encountered in the study area is part of the Waverly Group, of Mississippi age (Young, et al., 1996). The formations present at the locations of the piezometers included, from oldest to youngest, the Berea Formation, the Sunbury Formation and the Cuyahoga Formation. All of the boreholes logged were completed in the Cuyahoga Formation, which is the uppermost bedrock unit in the study area. The Cuyahoga Formation is a composed of shale and sandstone beds. Regionally, bedrock at dips towards the southeast at an angle of less than 0.5º (25 to 30 feet per mile) (Young, et al., 1996). Of particular interest was prominent a sandstone bed 1.8-2 feet thick, locally encountered at an approximate elevation of 680 feet, that has been referred to as the 680-foot Sandstone by the FBP personnel.

1.0 METHODOLOGY

A suite of borehole image logs was completed in each of the open boreholes.

The borehole image logs that were collected for this investigation include:

- Digital Acoustic Televiewer (ATV)
- Optical Televiewer (OPTV)
- Borehole Video

The ATV logs and the OPTV logs were acquired with a Mount Sopris Matrix logging system. The borehole video was recorded with a Well-Vu digital borehole video system.

1.1. ACOUSTIC TELEVIEWER (ATV) LOGS

The acoustic televiewer log provides an oriented high-resolution image of the borehole using high-resolution sound waves. The oriented image of the borehole can be presented in both amplitude and travel time. Results from this tool provide location and orientation information of features such as fractures, lithologic contacts and cavities, as well as relative smoothness of the sidewalls of the well bore. The relative smoothness of the well bore sidewalls can be used qualitatively in conjunction with other logs to assist with characterizing the bedrock lithology, or degree of weathering. The ATV digitizes up to 244 measurements around the borehole every 0.02 feet along the length of the borehole. Since the acquired image is digitized and properly oriented with respect to borehole deviation and tool rotation, it allows data processing to provide accurate strike and dip information of structural features. A fluid filled borehole is required to collect an ATV log. ATV logs can be acquired through murky, sediment laden, or opaque fluids. ATV logs cannot be acquired in an air filled well.

1.2. OPTICAL TELEVIEWER (OPTV) LOGS

The optical televiewer log provides an oriented, high-resolution, 360-degree photographic image of the borehole in either an air-filled, or water filled borehole. The OPTV tool is ineffective in wells that have a murky water column, or contains suspended sediment thus hindering water clarity. The oriented image of the borehole is presented in unwrapped format on the log. Results from this tool provide location, color, and orientation information of features such as fractures, lithologic contacts and cavities. The acquired image is digitized and properly oriented with respect to borehole deviation and tool rotation. Processing of the resulting image can provide accurate strike and dip information of fractures and other structural features.

1.3. BOREHOLE VIDEO LOGS

Borehole video is a downward looking video camera that provides a video record of the borehole. Video logging units provide an on-screen depth counter. Borehole video logs are useful for the visual inspection of lithologic changes, fracture identification, identification of contaminant staining, borehole construction inspection, and casing inspection. Video logs require good water clarity within the well to be useful. Video logs are not oriented with respect to north, so it is not possible to determine accurate orientations of fractures, bedding, or other bedrock structures.

2.0 RESULTS AND DISCUSSION

Piezometers WD-PZ-09C, WD-PZ-12C, WD-PZ-15C, WD-PZ-18C, WD-PZ-20C, and WD-SB-40 were logged during this investigation. All piezometers were 6-inch diameter, and had steel casing. WD-SB-40 was 4-inch PVC cased, and the uncased portion was 3.75-inch diameter.

Peizometers WD-PZ-09C and WD-PZ-12C had been previously logged with a suite of standard logs, and ATV. The logs from those boreholes were completed in 2011, and were presented and summarized in Document Submittal 0000059-22.

Prior to logging, the water levels in the boreholes were below the bottom of the casing. At each borehole, except WD-PZ-20C, borehole video and OPTV logs were completed, then the borehole was filled with water to allow collection of the ATV log. In WD-PZ-20C, the OPTV log was completed, then the ATV log was completed in the portion of the borehole below the standing water level. No water was added to WD-PZ-20C.

The bedrock encountered in each of the boreholes was predominantly fine-grained, thinly bedded shale, with occasional thin sandstone layers. The sandstone, when present, was most commonly less than 2 to 3 inches inches thick. The thickest sandstone bed encountered was the 680-foot Sandstone, that was approximately 1.8-2 feet thick. A prominent sandstone bed approximately 6 inches thick was also present approximately 2 feet below the base of the 680-foot Sandstone.

Overall, the quality of the borehole image logs was very good. The quality of the borehole video and the OPTV log were very clear in the air filled portions of the boreholes, and were slightly affected by the presence of suspended sediments below the water table. The borehole video was generally more sensitive to the presence of suspended sediments than the OPTV. The ATV logs are generally less sensitive to suspended sediments than the borehole video, or the OPTV, although heavily sediment laden liquids that are acoustically similar to the bedrock will produce little signal response.

The geophysical well logs are provided as an attachment to this report. Depths of all the logs are relative to the ground surface. Results and interpretations from the geophysical logs of each of the boreholes will be briefly described and discussed below.

2.1. WD-PZ-09C

Piezometer WD-PZ-09C had been logged previously with the ATV tool and the standard suite of logs that included a 3-arm caliper, natural gamma, single point resistance, 16-inch resistivity, 64-inch resistivity, and a calculated 40-inch lateral resistivity log. The bottom of casing is at a depth of approximately 30.8 feet. Water level in the well was at a depth of approximately 70.8 feet. The total depth of the borehole measured at the time of logging was 115.5 feet.

The 680-foot Sandstone extends from a depth of 78.8 feet to 80.8 feet. When logged in 2011, an anomalous feature was noted by reviewers in ATV log of the 680-foot Sandstone bed. The question was, was this anomalous feature a portion of a vertically oriented joint cross-cutting though the southwest side of the borehole. This anomalous feature was not observed in the shale above or below the sandstone, and there was no significant deflection of the 3-arm caliper that would indicate a widening of the borehole commonly observed if there is any significant open aperture associated with a fracture.

This same anomalous feature was again noted during completion of the ATV log during current logging activities, and was also observed in the OPTV log. Poor water clarity and glare from the LED light source for the video log kept this anomaly from being recognized in the video log. The OPTV log does indicate that this feature is likely related to a vertical joint the penetrates the 680-foot Sandstone bed, but not the adjacent shale above or below the sandstone. The OPTV log also indicates that potential iron staining occurs along this fracture.

A number of sandstone stringers and thin beds were present throughout the well, but no additional fractures were noted in the image logs of the bedrock.

2.2. WD-PZ-12C

Piezometer WD-PZ-12C was cased to a depth of 29.8 feet and has a total depth of approximately 81 feet. Standing water level was approximately 66 feet deep at the time of logging activities. WD-PZ-12C was also logged in 2011. When previously logged in 2011, the total depth was 73 feet, and it did not penetrated the 680-foot Sandstone layer. The borehole was deepened between 2011 and the time that the recent borehole image logs were completed to penetrate the 680-foot Sandstone. The 680-foot Sandstone was encountered during the current logging at a depth of 74.5-76.6 feet.

A potential vertical joint cross-cuts the 680-foot Sandstone, similar to that encountered in WD-PZ-09C. This joint is better defined than that observed in WD-PZ-09C, with fracturing clearly evident in the OPTV log. This fracture does not penetrate into the shale above or below the 680-foot Sandstone bed. There is also a potential bedding plane parting/fracture at the upper sandstone-to-shale interface of the 680-foot Sandstone recognizable in both the ATV and OPTV logs that appears to have a minor aperture, and could potentially transmit water. No additional fractures were recognized in any of the borehole logs.

2.3. WD-PZ-15C

Piezometer WD-PZ-15C was cased to a depth of 17 feet, with a total depth of 67.6 feet. Water was encountered at a depth of 42 feet. The borehole penetrated was predominantly shale with a number of thin sandstone stringers or lenses above the 680-foot Sandstone. The top of the 680-foot Sandstone was at a depth of 65.9 feet, and the bottom of the 680-foot Sandstone was not visible in the borehole before the bottom of the borehole was encountered.

No fractures were noted in the exposed portion of the 680-foot Sandstone, or in any of the other portions within this borehole.

2.4. WD-PZ-18C

Borehole WD-PZ-18C was cased to a depth of 13 feet, with a total depth of 94 feet. Water level prior to filling the borehole was at a depth of approximately 86.6 feet. Below the casing, the bedrock was weathered with fractures visible to a depth of approximately 26 feet. Between a depth of 26 feet and 33 feet, the bedrock was still visibly weathered, but noticeably less fractured. Below a depth of 33 feet the bedrock appeared to be un-weathered, and un-fractured.

The 680-foot Sandstone was encountered between 86.9 to 88.8 feet, and was not fractured at this location. The 6-inch thick sandstone bed below the 680-foot Sandstone was observed at a depth of 91.2 feet.

The OPTV log and the borehole video were collected before filling the borehole with water. Filling the borehole with water dislodged loose material from the weathered portion of the sidewall that settled to the bottom of this borehole. When completing the ATV log after filling the borehole with water, the ATV tool was only able to get a response to a depth of 88.8. Thick sediments appear to have settled to the base of the borehole making it impossible to get a response from the ATV tool below 88.8 feet.

2.5. WD-PZ-20C

WD-PZ-20C was logged to assist with the placement of grout in the bottom of the borehole. Although not originally scheduled to be logged, FBP requested that AGS inspect the bottom of the borehole to determine if any fractures were present that could allow grout to escape from the piezometer. WD-PZ-20C was logged with the OPTV tool, and the bottom several feet of the borehole was also logged with the ATV tool. No borehole video was completed, and no water was added to the borehole to allow an ATV log of the entire length of the borehole.

WD-PZ-20C had a total depth of 78.8 feet, and was cased to 18.8 feet. At the time the log was completed, there was a combination of water and grout present at a depth of 76.2 feet. The 680-foot Sandstone was located between 66 and 68 feet deep. Based on the OPTV log, the bedrock appears to be weathered to a depth of approximately 30 feet. Below the weathered zone, the bedrock was composed of shale with occasional sandstone stringers. No fractures were noted with the OPTV within the air filled portion of the borehole. It was not possible to get an OPTV image below the water table because of the poor clarity of the water/grout mixture in the bottom of the borehole. The ATV tool was run to inspect the water/grout filled portion of the borehole for the presence of any potential fractures. The water/grout mixture thickened as the bottom of the borehole was approached as indicated by the decreasing response from the ATV tool. No fractures were identified in the ATV log of the water/grout filled portion of the borehole.

2.6. *WD-SB-40*

Borehole WD-SB-40 was an open core-hole that was cased with 4-inch diameter PCV to a depth of 10.8 feet. Below the casing, the open hole was approximately 3.75 inches in diameter. Depth to the standing water level prior to adding water to the borehole was approximately 33 feet. Generally, the borehole video of this soil boring was of slightly better quality than the videos of the other boreholes encountered during this logging event because of the slightly narrower borehole diameter, and the hole had not been over-drilled following coring.

Borehole video and OPTV logs indicated that the bedrock from the bottom of casing to a depth of approximately 26 feet was weathered and had a number of nearly horizontal bedding plane fractures. The bedrock in the weathered zone appeared to consist of shale with numerous sandstone stringers. Between the depth of 28 and 30 feet there are three sandstone beds present that are each approximately 3-4 inches thick. Below 30 feet the sandstone beds become thinner and less frequent, but still easily identifiable.

The 680-foot Sandstone layer is between the depth of 71.8 and 72.7 feet. The common 6-inch sandstone layer beneath the 680-foot sandstone is at a depth of 75 feet.

Water was added to the top of the borehole to complete the ATV log The water quickly drained to a depth of 26 feet before the ATV log was collected. The vertical dark streaks present in the ATV log are the result of centering issues with the ATV tool within the borehole as a result in the decrease in hole diameter below the PVC casing. The centralizers were adjusted three times to try to improve the ATV log, and the log presented is the best result achieved. The ATV log clearly shows the locations of the sandstone layers within the boring.

3.0 SUMMARY AND CLOSING

Geophysical image well logs were completed in six boreholes located in Study Area D. Borehole image logs were completed in WD-PZ-09C, WD-PZ-12C, WD-PZ-15C, WD-PZ-18C, WD-PZ-20C, and WD-SB-40. The predominant lithology encountered was a fine grained, thinly bedded, friable shale with stringers of sandstone. A prominent, approximately 2-foot thick sandstone bed that had been described as the 680-foot Sandstone, because it is at an approximate elevation of 680 feet, was present in all boreholes logged.

Shallow, weathered bedrock zones were encountered in WD-PZ-18C, WD-PZ-20C, and WD-SB-40. These weathered zones did include some degree of bedrock fracturing. Generally, the un-weathered portions of all boreholes were free of bedrock fractures, with the exception of the 680-foot Sandstone encountered in WD-PZ-09C, and WD-PZ-12C, that had possible vertical oriented joints/fractures. These potential fractures did not appear to extend into the shale units above, or below the 680-foot Sandstone.

The data collection and interpretation methodologies used in this investigation are consistent with standard practices applied to similar geophysical investigations. The correlation of geophysical responses with probable subsurface features is based on the past results of similar surveys although it is possible that some variation could exist at this site.

REMARKS: This piezometer was logged to inspect the bottom portion portion of the borehole to determine if any fractures were present that might affect the placement of grout. The OPTV log was completed for the full length of the borehole, but could not image below the water/grout level in the borehole because of the lack of clarity. The ATV log was completed only below the existing water/grout level (no water was added to complete an entire ATV log).
No fractures were identified in either the OPTV or the ATV logs.

REMARKS: Casing Stick-up Height: 2 ft.
Well was filled with water following completion of OPTV log to allow collection of ATV log. After filling the water drained to a depth
of 26.3 ft. prior to completion of ATV log.
Dark vertical stripes in the ATV log were caused by having difficulty centralizing the ATV sonde within the core hole.

Kd profile for OSDC boreholes

Southwest Research Institute (SWRI) values are plotted. If unavailable, recalculated values are plotted.
Stratigraphy taken from columns provided by B. Phillips.

NOTES

Uranium results for Oct 31 and Nov 23 data generated by spiking groundwater at a U concentration of 100 ug/L. SW Research Uranium results for Aug 31 and Sep 28 invalid due to U concentration in contact solution being too low (5 ug/L).

Tc-99 Contaminated groundwater for Nov 23 contact solution = 783 pCi/L; for Oct 31 = 663 pCi/L; for Sep 28 = 195 pCi/L; Aug 31 = 154 pCi/L.

Recalculated values will be different than SWRI results when in situ values are calculated (see red text below charts and red numbers) and when the standard equivalence test indicates that the SWRI pooled values for a solid sample used to calculate the Kd are not equivalent, which results in elimination of one or more of the results used to calculate the SWRI reported Kd value.

Uranium Kd charts are below Tc-99 charts

Re: DBS&A Laboratory Report for Fluor-B&W Portsmouth LLC - PO-0001160/Charge Number DEAC30.0002.00.01.7201

Dear Ms. Jones:

Enclosed is the final report for Fluor-B&W Portsmouth LLC - PO-0001160/Charge Number DEAC30.0002.00.01.7201 samples. Please review this report and provide any comments as samples will be held for a maximum of 30 days. After 30 days samples will be returned or disposed of in an appropriate manner.

All testing results were evaluated subjectively for consistency and reasonableness, and the results appear to be reasonably representative of the material tested. However, DBS&A does not assume any responsibility for interpretations or analyses based on the data enclosed, nor can we guarantee that these data are fully representative of the undisturbed materials at the field site. We recommend that careful evaluation of these laboratory results be made for your particular application.

The testing utilized to generate the enclosed final report employs methods that are standard for the industry. The results do not constitute a professional opinion by DBS&A, nor can the results affect any professional or expert opinions rendered with respect thereto by DBS&A. You have acknowledged that all the testing undertaken by us, and the final report provided, constitutes mere test results using standardized methods, and cannot be used to disqualify DBS&A from rendering any professional or expert opinion, having waived any claim of conflict of interest by DBS&A.

We are pleased to provide this service to Fluor-B&W Portsmouth LLC and look forward to future laboratory testing on other projects. If you have any questions about the enclosed data, please do not hesitate to call.

Sincerely,

DANIEL B. STEPHENS & ASSOCIATES, INC.

[1] G = Gravimetric Moisture Content, VM = Volume Measurement Method, VD = Volume Displacement Method

[2] CH = Constant Head Rigid Wall, FH = Falling Head Rigid Wall, FW = Falling Head Rising Tail Flexible Wall

[3] HC = Hanging Column, PP = Pressure Plate, FP = Filter Paper, DPP = Dew Point Potentiometer, RH = Relative Humidity Box, EP = Effective Porosity, WHC = Water Holding Capacity, Kunsat = Calculated Unsaturated Hydraulic Conductivity

[4] DS = Dry Sieve, WS = Wet Sieve, H = Hydrometer

[5] F = Fine (<4.75mm), C = Coarse (>4.75mm)

Notes

Thirteen core samples arrived on September 2, 2011, each wrapped in plastic wrap, foil, and 1-gallon ziploc bags sealed with tape. The samples arrived in good order surrounded by packing material in three large coolers.

Saturated hydraulic conductivity was measured for all samples via the flexible wall method, as requested. Separate samples were placed in silicone inside rigid testing rings for air permeability and moisture retention testing. Several of the rigid wall sub-samples did not produce visible outflow during saturation using the rigid-wall apparatus. These samples were saturated via the flexible wall apparatus prior to initiating moisture retention testing.

The volume and specific gravity of the flexible wall sub-samples were measured based on the measured saturated sample mass in water and in air. The dry bulk density of these sub-samples was then calculated using the measured oven dry mass. For consistency, the measured density of the flexible wall sub-sample was also applied to the corresponding rigid wall sub-sample that was used for moisture retention testing and air permeability measurements and calculations.

Moisture retention properties measurements via the dewpoint potentiometer were inappropriate, and therefore not reported, for several of the samples.

The van Genuchten modeling parameters provided in this report were obtained based on the measured moisture retention points using the RETC code for quantifying the hydraulic functions of unsaturated soils. Readers of this report are encouraged to independently evaluate the data and note that modeling parameters may be generated using other means, if desired.

Air permeability of the samples was measured at the ‘as receive’ moisture content and at the oven dry state using the rigid wall sub-sample. The air permeability measurements of the samples at the as received state contained moisture, though the air permeability test is applicable for oven dry material. And, several of the samples had visible fractures at the oven dry state, leading to suspected preferential air flow during testing, as noted on the air permeability report sheets.

Calculated relative nonwetting phase (air) permeability as a function of wetting phase (water) saturation was calculated for the samples at each reported moisture retention point. The van Genuchten model for calculating air permeability was used, this is the most commonly used method, based on measured flexible wall saturated hydraulic conductivity and the measured moisture retention properties.

Summary of Sample Preparation/Volume Changes

	Initial Sample Data[1]		Volume Change Post Saturation[2]			Volume Change Post Drying Curve[3]

[1] Initial Sample Data: The 'as received' dry bulk density and moisture content.

[2] Volume Change Post Saturation: Volume change measurements were obtained after saturated hydraulic conductivity testing.

[3] Volume Change Post Drying Curve: Volume change measurements were obtained throughout hanging column and pressure plate testing. The 'Volume Change Post Drying Curve' values represent the final sample dimensions after the last pressure plate point.

Notes:

"+" indicates sample swelling, "-" indicates sample settling, and "---" indicates no volume change occurred.

Moisture Retention Data

Hanging Column / Pressure Plate

(Soil-Water Characteristic Curve)

Job Name: Fluor-B&W Portsmouth LLC
Job Number: LB11.0188.00
Sample Number: B007RC50.0-51.0
Date Sampled: 8/26/11
Depth: 50.0-51.0

Dry wt. of sample (g)*:* 290.77
Tare wt., ring (g)*:* 0.00
Tare wt., screen & clamp (g)*:* 0.00
Initial sample volume (cm^3)*:* 123.78
Initial dry bulk density (g/cm^3)*:* 2.35
Measured particle density (g/cm^3)*:* 2.73
Initial calculated total porosity (%)*:* 14.01

	Date	Time	Weight* (g)	Matric Potential (-cm water)	Moisture Content[†] (% vol)
Hanging column:	11-Oct-11	12:30	307.92	0	13.86
	18-Oct-11	9:20	307.70	63.0	13.68
	25-Oct-11	13:40	307.31	186.0	13.36
Pressure plate:	7-Nov-11	7:45	307.20	337	13.27
	19-Nov-11	12:15	307.12	1275	13.21

Volume Adjusted Data[1]

	Matric Potential (-cm water)	Adjusted Volume (cm^3)	% Volume Change[2] (%)	Adjusted Density (g/cm^3)	Adjusted Calculated Porosity (%)
Hanging column:	0.0	---	---	---	---
	63.0	---	---	---	---
	186.0	---	---	---	---
Pressure plate:	337	---	---	---	---
	1275	---	---	---	---

Comments:

[1] Applicable if the sample experienced volume changes during testing. ‘Volume Adjusted’ values represent each of the volume change measurements obtained after saturated hydraulic conductivity testing and throughout hanging column/pressure plate testing. "---" indicates no volume changes occurred.

[2] Represents percent volume change from original sample volume. A '+' denotes measured sample swelling, a '-' denotes measured sample settling, and '---' denotes no volume change occurred.

* Weight including tares

[†] Assumed density of water is 1.0 g/cm^3

[‡‡] Volume adjustments are applicable at this matric potential (see comment #1). Changes in volume, if applicable, are estimated based on obtainable measurements of changes in sample length and diameter.

Relative humidity box:	857025	---	---	---	---

Comments:

[1] Applicable if the sample experienced volume changes during testing. ‘Volume Adjusted’ values represent the volume change measurements obtained after the last hanging column or pressure plate point. "---" indicates no volume changes occurred.

[2] Represents percent volume change from original sample volume. A '+' denotes measured sample swelling, a '-' denotes measured sample settling, and '---' denotes no volume change occurred.

* Weight including tares

† Adjusted for >2.00mm (#10 sieve) material not used in DPP/RH testing. Assumed moisture content of material >2.00mm is zero, and assumed density of water is 1.0 g/cm^3.

‡‡ Volume adjustments are applicable at this matric potential (see comment #1). Changes in volume, if applicable, are estimated based on obtainable measurements of changes in sample length and diameter.

INORGANICS ANALYSIS

The Distribution Coefficients (K_d) for Tc-99 and Total Uranium (U) were determined using the following modification to ASTM C1733.

The contact solution was be prepared by mixing two contaminated ground waters immediately prior to testing. The groundwater contaminated with Tc-99 (749-EPE-02) contained a significant amount of sediment and was filtered through a Whatman #1810-125 acid treated TCLP filter prior to combining at a 50:50 ratio, by mass, with the uranium contaminated groundwater (231A-01G-01). Only the minimum volume needed for the sample batch was prepared. Samples were weighted in duplicate for 8 time points (24 hr, 48 hr, Day 4, Day 7, Day 10, Day 14, Day 21 and Day X). The method specifies a 1:25 soil to contact solution test ratio; therefore, 200 mL of contact solution was added to 8 g of soil in a 250-mL Nalgene bottle. Samples were tumbled using the TCLP tumbler for 12-hours a day. For each time point, a 200 mL of the contact solution was added to an empty Nalgene and processed alongside the sample as a time point "Blank" for each Day n.

At each time point, the sample duplicates and time point "Blank" were filtered using a Whatman #1810-125 acid treated TCLP filter. The filtrate was preserved with nitric acid and stored for analysis. After the 5th time point (Day 10), all samples and "Blanks" were submitted for Tc-99 and total uranium analysis.

To calculate Kd in C1733, the following equation is used:

$$K_d = \frac{\frac{(C_s\,x\,V) - (C_f\,x\,V)}{m}}{C_f}$$

Where:
Cs = Starting Concentration of analyte of interest in contact solution
Cf = Final Concentration of analyte of interest in contact solution
V = Total Volume of contact liquid (mL)
m = Dry Mass of Solid (g)

For the purposes of this modified analysis at multiple time points, the concentrations of all "Blanks" analyzed were averaged and used as the starting concentration of the contact solution. The samples were not dried prior to the sample analysis; therefore, a percent solids was performed, and the results are reported on a dry weight basis. Therefore, following equation was used:

$$K_d = \frac{\frac{(C_{avg\ blk}\,x\,V) - (C_{day\,x}\,x\,V)}{m\ x\ \%\ soilds}}{C_{day\,x}}$$

Client: Fluor-B&W Portsmouth LLC
SDG: 469498
SwRI Project Number: 16526.05.00X
SwRI Task Order Number: 110614-8

Where:
$C_{avg\ blk}$ = average "Blank" concentration which represents the starting concentration of analyte of interest in contact solution
$C_{day\ x}$ = concentration of analyte of interest in contact solution at time point x
V = total volume of contact liquid (mL)
m = weight of Solid (g)

In addition to the K_d values, the propagated uncertainties were also calculated. The K_d values and the uncertainties for the sample duplicates were averaged for each time point. By evaluating these values, it was established when the Tc-99 and U sorption equilibrium had been reached. With the exception of for sample WDPZ05-06-2.0 (SwRI #469500), all samples had reached equilibrium by Day 10. Since just the Total U had not reach equilibrium by Day 10, the total uranium analysis of Day 14 and Day 21 sample duplicates and blanks was necessary for SwRI #469500.

The final K_d value reported is an average of all K_d time points values once equilibrium was achieved. The uncertainty reported was also the average from these time points. For Tc-99, equilibrium was achieved by Day 2; therefore, the final K_d and uncertainties values are the averages of Days 2-10. With the exception of SwRI #469500, the uranium sorption reached equilibrium by Day 4; therefore, the average of Days 4-10 was reported. For SwRI #469500, the uranium sorption reached equilibrium by Day 14; therefore, the average of Days 14 and 21 was reported.

TOTAL URANIUM ANALYSIS

The acidified leachates were analyzed directly (no digestion was required) for total uranium by ICP-MS. All instrument QC criteria were met. The percent recoveries for the initial and continuing calibration verifications were within 90-110%. Total uranium was not detected above SwRI's reporting limit in the initial and continuing calibration blanks. The low level, CRI standard recoveries were within 50-150%. The percent recoveries for the interference check sample ICSABs were within 80-120%. The internal standard recoveries were within 80-120% for the ICV/CCV/ICB/CCBs and within 30-120% for all samples.

RADIOLOGICAL ANALYSIS

The sample SDG 469498 consisted of seven soil samples received for radiological analysis. The water samples for radiological analysis were reported on an "as received" basis. The recommended sample holding time of six months was met.

The sample was analyzed for the following:

Matrix	Analysis	Method
Soil	^{99}Technetium	Liquid Scintillation Spectroscopy

^{99}Technetium

A 100ml aliquot of each sample fraction was analyzed for ^{99}Technetium. The sample aliquots were digested at 80°C for 4 hours with nitric acid and then one additional hour with hydrogen peroxide. The aliquots were then brought to a final volume of 50ml and then chemically separated using resins. A preparation blank and two laboratory control samples were analyzed with each sample batch. Each sample fraction was analyzed in duplicate.

For all liquid scintillation analysis, the daily instrument performance checks were within the running statistical control limits.

For ^{99}Tc analysis, the ^{99}Tc was separated from the digestion using chemical separation resins. After chemical separation, the resin containing the ^{99}Tc was placed into a liquid scintillation vial and 15 ml of scintillation cocktail was added. The samples were counted on a liquid scintillation counter programmed to count only the ^{99}Tc region of interest. The liquid scintillation counter ^{99}Tc program was standardized using ^{99}Tc as the radioisotope to establish a specific efficiency quench curve. Four preparation blanks and eight laboratory control samples were analyzed with the sample batches. The preparation blank result for SwRI sample ID PBWG26JV1 was less than 1.65 times the TPU, the MDA, and the RL. The preparation blank results for SwRI sample ID PBWG25JV1, PBWG25JV2, and PBWG26JV2 were greater than 1.65 times the TPU, but were less than the MDA and the RL. The results for all of the laboratory control samples were within the recovery control limits of 75-125%. Each sample fraction was analyzed in duplicate and the sample duplicate evaluation ratio was less than three for all duplicates. A matrix spike and matrix spike duplicate were not performed with any of the analyses.

"I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed above. Release of the data contained in this hardcopy data package and in the computer-readable data submitted on diskette has been authorized by the laboratory manager or his/her designee, as verified by the following signature. This report shall not be reproduced except in full without the written approval of SwRI."

Duplicate Evaluation = (Sample-Duplicate) / sqrt ((TPUsample^2) + (TPUdup^2)) ≤ 3

TPU Factors	**%**
Aliquot Amount	2.00%
Standards	5.00%
Quench Curve	0.50%
Sub Sampling	2%
TPU of net Counts	**5.77%**

```
Assay Definition

Assay Description:

Assay Type: DPM (Single)
Report Name: Report1
Output Data Path: C:\Packard\Tricarb\Results\Default\99tc_dpm\20110727_1111\Replay_20110825_134149
Raw Results Path: C:\Packard\Tricarb\Results\Default\99tc_dpm\20110727_1111\20110727_1111.results
Assay File Name: C:\Packard\TriCarb\Assays\99tc_dpm.lsa

Count Conditions

Nuclide: 99tc
   Quench Indicator: tSIE/AEC
   External Std Terminator (sec): 10 sec
   Pre-Count Delay (min): 0.00
Quench Set:
   Low Energy: 99Tc
Count Time (min): 60.00
Count Mode: Normal
Assay Count Cycles: 1         Repeat Sample Count: 1
#Vials/Sample: 1              Calculate % Reference: Off

Background Subtract

Background Subtract: Off
Low CPM Threshold: Off
2 Sigma % Terminator: Off

Regions          LL       UL
A               0.0    292.0
B               0.0    292.0
C               0.0   2000.0

Count Corrections

Static Controller: On          Luminescence Correction: On
Colored Samples: On            Heterogeneity Monitor: Off
Coincidence Time (nsec): 18    Delay Before Burst (nsec): 75

Certificate

Standard Reference Material 4288A
Technetium-99 Radioactivity Standard

DATE RECEIVED: 9/25/01
DATE EXPIRED: Sept 2006 OK
DATE OPENED: 10/1/01
INDEX: 3082 PO: C[illegible]

This Standard Reference Material (SRM) consists of radioactive technetium-99, as potassium pertechnetate, and potassium hydroxide dissolved in 5 mL of distilled water. The solution is contained in a flame-sealed NIST borosilicate-glass ampoule. The SRM is intended for the calibration of beta-particle counting instruments and for the monitoring of radiochemical procedures.

Radiological Hazard

The SRM ampoule contains technetium-99 with a total activity of approximately 160 kBq. Technetium-99 decays by beta-particle emission. None of the beta particles escape from the SRM ampoule. During the decay process no photons are emitted. Approximate unshielded dose rates at several distances (as of the reference time) are given in note [a]*. There is no detectable external radiation. The SRM should be used only by persons qualified to handle radioactive material.

Chemical Hazard

The SRM ampoule contains potassium hydroxide (KOH) with a concentration of 0.001 moles per liter of water. The solution is mildly corrosive and could represent a health hazard if it comes in contact with eyes or skin. If the ampoule is to be opened to transfer the solution, the recommended procedure is given on page 2.

Storage and Handling

The SRM should be stored and used at a temperature between 5 and 65 °C. The solution in an unopened ampoule should remain stable and homogeneous until at least September 2006.

The ampoule (or any subsequent container) should always be clearly marked as containing radioactive material. If the ampoule is transported it should be packed, marked, labeled, and shipped in accordance with the applicable national, international, and carrier regulations. The solution in the ampoule is a dangerous good (hazardous material) because of the radioactivity.

Preparation

This Standard Reference Material was prepared in the Physics Laboratory, Ionizing Radiation Division, Radioactivity Group, J.M.R. Hutchinson, Group Leader. The overall technical direction and physical measurements leading to certification were provided by L.L. Lucas of the Radioactivity Group.

The support aspects involved in the preparation, certification, and issuance of this SRM were coordinated through the Standard Reference Materials Program by N.M. Trahey.

010324

Recommended Procedure for Opening the SRM Ampoule

1) If the SRM solution is to be diluted, it is recommended that the diluting solution have a composition comparable to that of the SRM solution.

2) Wear eye protection, gloves, and protective clothing and work over a tray with absorbent paper in it.

3) Shake the ampoule to wet all of the inside surface of the ampoule. Return the ampoule to the upright position.

4) Check that all of the liquid has drained out of the neck of the ampoule. If necessary, gently tap the neck to speed the process.

5) Holding the ampoule upright, score the narrowest part of the neck with a scribe or diamond pencil.

6) Lightly wet the scored line. This reduces the crack propagation velocity and makes for a cleaner break.

7) Hold the ampoule upright with a paper towel, a wiper, or a support jig. Position the scored line away from you. Using a paper towel or wiper to avoid contamination, snap off the top of the ampoule by pressing the narrowest part of the neck away from you while pulling the tip of the ampoule towards you.

8) Transfer the solution from the ampoule using a pycnometer or a pipet with dispenser handle. NEVER PIPETTE BY MOUTH.

9) Seal any unused SRM solution in a flame-sealed glass ampoule, if possible, to minimize the evaporation loss. See also reference [4]*.

---

PROPERTIES OF SRM 4288A
(Certified values are shown in bold type)

Source identification number	NIST SRM 4288A		
Physical Properties:			
Source description	Liquid in flame-sealed NIST borosilicate-glass ampoule		
Ampoule specifications	Body outside diameter (16.5 ± 0.5) mm Wall Thickness (0.60 ± 0.04) mm Barium content Less than 2.5% Lead-oxide content Less than 0.02% Other heavy elements Trace quantities		
Solution density	(0.998 ± 0.002) g·mL^{-1} at 21 °C [b]*		
Solution mass	(4.998 ± 0.002) g [b]		
Chemical Properties:			
Solution composition	Chemical Formula	Concentration (mol·L^{-1})	Mass Fraction (g·g^{-1})
	H_2O KOH $K^{99}TcO_4$	55 0.001 0.0005	1.00 0.00006 0.0001
Radiological Properties:			
Radionuclide	Technetium-99		
Reference time	1200 EST, 1 September 1996		
Massic activity of the solution [c]	32.61 kBq·g^{-1}		
Relative expanded uncertainty (k=2)	1.14% [d] [e]		
Photon-emitting impurities	None detected [f]		
Half lives used in the decay corrections	Cobalt-60: (5.2714 ± 0.0005) a [g] Technetium-99: (2.111 ± 0.012) × 10^5 a [g]		
Measuring instrument	NIST 4πβ(LS)-γ-anticoincidence counting system using cobalt-60 as the efficiency-tracing radionuclide. The efficiency was varied electronically from 50 to 93 percent.

NOTES

[a] The Sievert is the SI unit for dose equivalent. See reference [1]. One μSv is equal to 0.1 mrem.

Distance from Ampoule (cm):	1	30	100
Approximate Dose Rate (μSv/h):	<0.1		(Not detectable)

[b] The stated uncertainty is two times the standard uncertainty.

[c] Massic activity is the preferred name for the quantity activity divided by the total mass of the sample. See reference [1].

[d] The reported value, y, of massic activity (activity per unit mass) at the reference time was not measured directly but was derived from measurements and calculations of other quantities. This can be expressed as $y = f(x_1, x_2, x_3, \ldots x_n)$, where f is a mathematical function derived from the assumed model of the measurement process.

The value, x_i, used for each input quantity i has a standard uncertainty, $u(x_i)$, that generates a corresponding uncertainty in y, $u_i(y) = |\partial y/\partial x_i| \cdot u(x_i)$, called a component of combined standard uncertainty of y.

The combined standard uncertainty of y, $u_c(y)$, is the positive square root of the sum of the squares of the components of combined standard uncertainty.

The combined standard uncertainty is multiplied by a coverage factor of $k = 2$ to obtain U, the expanded uncertainty of y.

Since it can be assumed that the possible estimated values of the massic activity are approximately normally distributed with approximate standard deviation $u_c(y)$, the unknown value of the massic activity is believed to lie in the interval $y \pm U$ with a level of confidence of approximately 95 percent.

For further information on the expression of uncertainties, see references [2] and [3].

[e] The value of each standard uncertainty component, and hence the value of the expanded uncertainty itself, is a best estimate based upon all available information, but is only approximately known. That is to say, the "uncertainty of the uncertainty" is large and not well known. This is true for uncertainties evaluated by statistical methods (e.g., the relative standard deviation of the standard deviation of the mean for the liquid-scintillation counting is approximately 50%) and for uncertainties evaluated by other methods (which could easily be over estimated or under estimated by substantial amounts). The unknown value of the expanded uncertainty is believed to lie in the interval $U/2$ to $2U$ (i.e., within a factor of 2 of the estimated value).

[f] Estimated limits of detection for photon-emitting impurities are:
$2 \times 10^{-4}\ \gamma \cdot s^{-1} \cdot g^{-1}$ for energies between 20 and 85 keV,
$2 \times 10^{-5}\ \gamma \cdot s^{-1} \cdot g^{-1}$ for energies between 93 and 503 keV,
$1 \times 10^{-5}\ \gamma \cdot s^{-1} \cdot g^{-1}$ for energies between 519 and 1457 keV, and
$5 \times 10^{-6}\ \gamma \cdot s^{-1} \cdot g^{-1}$ for energies between 1465 and 3250 keV.

[g] The stated uncertainty is the standard uncertainty. See reference [5].

[h] Relative standard uncertainty of the input quantity x_i.

[i] The relative change in the output quantity y divided by the relative change in the input quantity x_i. If $|\partial y/\partial x_i| \cdot (x_i/y) = 1.0$, then a 1% change in x_i results in a 1% change in y. If $|\partial y/\partial x_i| \cdot (x_i/y) = 0.05$, then a 1% change in x_i results in a 0.05% change in y.

[j] Relative component of combined standard uncertainty of output quantity y, rounded to two significant figures or less. The relative component of combined standard uncertainty of y is given by $u_i(y)/y = |\partial y/\partial x_i| \cdot u(x_i)/y = |\partial y/\partial x_i| \cdot (x_i/y) \cdot u(x_i)/x_i$. The numerical values of $u(x_i)/x_i$, $|\partial y/\partial x_i| \cdot (x_i/y)$, and $u_i(y)/y$, all dimensionless quantities, are listed in columns 3, 4, and 5, respectively. Thus, the value in column 5 is equal to the value in column 4 multiplied by the value in column 3. The input quantities are independent, or very nearly so. Hence the covariances are zero or negligible.

[k] The relative standard uncertainty of $\lambda \cdot t$ is determined by the relative standard uncertainty of λ (i.e., of the half life). The relative standard uncertainty of t is negligible.

[m] $|\partial y/\partial x_i| \cdot (x_i/y) = |\lambda \cdot t|$, multiplied by other sensitivity factors where appropriate.

[n] The live time is determined by counting the pulses from a gated crystal-controlled oscillator.

[p] The standard uncertainty for each undetected impurity that might reasonably be expected to be present is estimated to be equal to the estimated limit of detection for that impurity, i.e. $u(x_i)/x_i$ = 100%. $|\partial y/\partial x_i| \cdot (x_i/y)$ = {(response per Bq of impurity)/(response per Bq of Tc-99)}·{(Bq of impurity)/(Bq of Tc-99)}. Thus $u_i(y)/y$ is the relative change in y if the impurity were present with a massic activity equal to the estimated limit of detection.

1. The **Certified Value** is the actual "made-to" concentration confirmed by ERA analytical verification.

2. The stated **Uncertainty** is the total propagated uncertainty at the 95% confidence interval. The uncertainty is based on the preparation and internal analytical verification of the product by ERA, times a coverage factor which is equal to the student t factor at a 95% confidance interval at n-1 degrees of freedom.

3. The **QC Performance Acceptance Limits (QC PALs™)** are based on actual historical data collected in ERA's Proficiency Testing program. The **QC PALs™** reflect any inherent biases in the methods used to establish the limits and closely approximate a 95% confidence interval of the performance that experienced laboratories should achieve using accepted environmental methods. Use the **QC PALs™** to realistically evaluate your performance against your peers.

4. The **PT Performance Acceptance Limits (PT PALs™)** are calculated using the regression equations and fixed acceptance criteria specified in the NELAC proficiency testing requirements. Use the **PT PALs™** when analyzing this QC standard alongside USEPA and NELAC compliant PT standards. Please note that many PT study acceptance limits are concentration dependent (some non-linearly) and, therefore, the acceptance limits of this QC standard and any PT standard may differ relative to their difference in concentrations.

5. The **Analytical Verification** data include the mean value, percent recovery and number of data points reported by the laboratories in our Proficiency Testing study compared to the Certified Values. In addition, where NIST Standard Reference Materials (SRMs) are available, each analyte has been analytically traced to the NIST SRM listed.

Traceability Recovery (%) = [(% recovery certified standard)/(% recovery NIST SRM)]*100

The traceability data shown were compiled by analyzing the ERA standards or their associated stock solutions against the applicable NIST SRMs.

6. This standard **expires 3/2012.** The certified values are monitored and purchasers will be notified of any significant changes resulting in recertification or withdrawal of this certifiad reference material during the period of validity of this certificete.

If you have any questions or need technical assistance, please cell ERA technical assistance at 1-800-372-0122 or email to info@eraqc.com.

INORGANICS ANALYSIS

The Distribution Coefficients (K_d) for Tc-99 and Total Uranium (U) were determined using the following modification to ASTM C1733.

The contact solution was be prepared by spiking the client provided Tc-99 contaminated groundwater, which had been filtered through a Whatman #1810-125 acid treated TCLP filter, at 100 ppb Uranium. (Tc-99 groundwaters 749-WPW-03, 749-WPW-04 and 749-WPW-05 were used). Only the minimum volume needed for the sample batch was prepared. Samples were weighted in duplicate for 5 time points (Day 7, Day 10, Day 14, Day 21 and Day X). The method specifies a 1:25 soil to contact solution test ratio; therefore, 200 mL of contact solution was added to 8 g of soil in a 250-mL Nalgene bottle. Samples were tumbled using the TCLP tumbler for 12-hours a day. For each time point, a 200 mL of the contact solution was added to an empty Nalgene and processed alongside the sample as a time point "Blank" for each Day n.

At each time point, the sample duplicates and time point "Blank" were filtered using a Whatman #1810-125 acid treated TCLP filter. The filtrate was preserved with nitric acid and stored for analysis. After the 4th time point (Day 21), all samples and "Blanks" were submitted for Tc-99 and total uranium analysis. Please note that the Day 10 time point was inadvertently pulled on Day 9.

To calculate Kd in C1733, the following equation is used:

$$K_d = \frac{\frac{(C_s \, x \, V) - (C_f \, x \, V)}{m}}{C_f}$$

Where:
Cs = Starting Concentration of analyte of interest in contact solution
Cf = Final Concentration of analyte of interest in contact solution
V = Total Volume of contact liquid (mL)
m = Dry Mass of Solid (g)

For the purposes of this modified analysis at multiple time points, the concentrations of all "Blanks" analyzed were averaged and used as the starting concentration of the contact solution. The samples were not dried prior to the sample analysis; therefore, a percent solids was performed, and the results are reported on a dry weight basis. Therefore, following equation was used:

$$K_d = \frac{\frac{(C_{avg\,blk} \, x \, V) - (C_{day\,x} \, x \, V)}{m \, x \, \% \, soilds}}{C_{day\,x}}$$

Client: Fluor-B&W Portsmouth LLC
SDG: 473754
SwRI Project Number: 16526.05.00X
SwRI Task Order Number: 110825-10

Where:
$C_{avg\ blk}$ = average "Blank" concentration which represents the starting concentration of analyte of interest in contact solution
$C_{day\ x}$ = concentration of analyte of interest in contact solution at time point x
V = total volume of contact liquid (mL)
m = weight of Solid (g)

In addition to the K_d values, the propagated uncertainties were also calculated. The K_d values and the uncertainties for the sample duplicates were averaged for each time point. By evaluating these values, it was established when the Tc-99 and U sorption equilibrium had been reached. It was determined that all samples had reached equilibrium by Day 21; therefore, the analysis of Day X was not necessary.

The final K_d value reported is an average of all K_d time points values once equilibrium was achieved. With the exception of SwRI ID #473758 (WDSB02-07-4.5), it appeared that equilibrium was reached by the first time point (Day 7). Therefore, the final K_d and uncertainties values are the averages of Days 7-21. Equilibrium wasn't reached until Day 14; average of Days 14 and 21 was reported. Also, SwRI ID #473757 (WDSB02-07-24.5) contained two outliers compared to the time points and replicates; therefore, they were not used in the K_d calculation/

RADIOLOGICAL ANALYSIS

The sample SDG 473754 consisted of eleven soil samples received for radiological analysis. The soil samples for radiological analysis were reported on an "as received" basis. The recommended sample holding time of six months was met.

The samples were analyzed for the following:

Matrix	Analysis	Method
Soil	^{99}Technetium	Liquid Scintillation Spectroscopy

^{99}Technetium

A 100ml aliquot of each sample fraction was analyzed for ^{99}Technetium. The sample aliquots were digested at 80°C for 4 hours with nitric acid and then one additional hour with hydrogen peroxide. The aliquots were then brought to a final volume of 50ml and then chemically separated using resins. A preparation blank and two laboratory control samples were analyzed with each sample batch. Each sample fraction was analyzed in duplicate.

For all liquid scintillation analysis, the daily instrument performance checks were within the running statistical control limits.

For ^{99}Tc analysis, the ^{99}Tc was separated from the digestion using chemical separation resins. After chemical separation, the resin containing the ^{99}Tc was placed into a liquid scintillation vial and 15 ml of scintillation cocktail was added. The samples were counted on a liquid scintillation counter programmed to count only the ^{99}Tc region of interest. The liquid scintillation counter ^{99}Tc program was standardized using ^{99}Tc as the radioisotope to establish a specific efficiency quench curve. A total of eight preparation blanks and sixteen laboratory control samples were analyzed with the sample batches. All of the results for the preparation blanks were less than 1.65 times the TPU, the MDA, and the RL with the exception of SwRI sample ID PBWK11JV1. The preparation blank result for SwRI sample ID PBWK11JV1 was greater than 1.65 times the TPU, but was less than the MDA and the RL. The results for all of the laboratory control samples were within the recovery control limits of 75-125%. Each sample fraction was analyzed in duplicate and the sample duplicate evaluation ratio was less than three for all duplicates. A matrix spike and matrix spike duplicate were not performed with any of the analyses.

TOTAL URANIUM ANALYSIS

The acidified leachates were analyzed directly (no digestion was required) for total uranium by ICP-MS. All instrument QC criteria were met. The percent recoveries for the initial and continuing calibration verifications were within 90-110%. Total uranium was not detected above SwRI's reporting limit in the initial and continuing calibration blanks. The low level, CRI standard recoveries were within 50-150%. The percent recoveries for the interference check sample ICSABs were within 80-120%. The internal standard recoveries were within 80-120% for the ICV/CCV/ICB/CCBs and within 30-120% for all samples.

Laboratory Task Order

TO #: 110825-10 Revision: 1

Project(s): 16526.05.00X
Manager(s): DAMMANN, MIKE
To PM: 09/20/11
To QA: 09/20/11
To Client: 09/21/11

SDG: 473754
VTSR: 08/25/11
CASE: FXP02234L04

SRR #'s: 45484, 45511
Client(s): Fluor-B&W Portsmouth LLC

Instructions

FLUOR-B&W PORTSMOUTH LLC. SOW FXP02234L04. Project OSDC
SDG is 473754. SDG IS CLOSED.

28-day TAT HARDCOPY. Using 26-day TAT for Report/EDD.
FINAL DATA/HARDCOPY IS DUE TO THE CLIENT ON 09/22/11.

26 overall SO samples (26 containers) received on 08/25/11 for SOW FXP02234L04.
OUT of the 26 samples, only the 11 SOIL samples for DISTRIBUTION COEFFICIENT are listed in this task order.

see SOW for full compound list, CRDLs and RLs:
ASTM C1733 Distribution Coefficients
Tc-99 LSC - Technetium-99 (to support ASTM C1733; see summary)
Total U by ICP-MS (to support ASTM C1733; see summary)

EDD REQUIRED. FORMS PLUS RAW DATA PACKAGE REQUIRED.

PROJECT DESCRIPTION _ Change Order #3 _ Characterization to Support Siting of On-Site Disposal Facility
ELECTRONIC DATA DELIVERABLE _ Electronic Deliverable (AMSED) uploaded into PEMS via the internet plus CD.
QC REQUIREMENTS _ Per ICPT BOA/QSAS and method requirements.
SMO representative is Jim Applegate James.Applegate@fbports.com; 740.897.4081
Additional contact is Gerald Fulkerson 740 897 2588, Gerald.Fulkerson@fbports.com.
****
Report ORIGINAL & CD Results to:

FLUOR-B&W PORTSMOUTH LLC.

LSC Bench Sheet

Tc-99

Client: Fluor-B&W Portsmouth
Task Order: 110825-10, 110915-9
Prep Page: 12-192
Prep Date: 3-Oct-11

Project #: 16526.05.00X
SRR: 45511, 45412
RL: 20 pCi/L
Units: L

Sample Calculations
dpm = cpm / (eff-1 / 100) - avg bkg dpm
Activity pCi/g = dpm * DF / 2.22 (dpm to pCi)
TPU pCi/L =SQRT(Counting Error^2+ (systematic TPU% /100) ^2*Sample Activity^2)
MDC pCi/g = (4.65*SQRT((AVG(bkg cpm))/time)/((Eff / 100)*Sample Amt)/2.22+3/(Eff /100*Sample Amt* Time))/ 2.22
Counting Error = SQRT(cpm/time + bkg cpm/bkg time)/ Sample Amount / (Eff/100 * 2.22)
(RPD) = Abs Value(Sample-Duplicate) / ((Sample + Duplicate) / 2) * 100
Duplicate Evaluation = (Sample-Duplicate) / sqrt ((TPUsample^2) + (TPUdup^2)) ≤ 3

TPU Factors	%
Aliquot Amount	2.00%
Standards	5.00%
Quench Curve	0.50%
Sub Sampling	2%
TPU of net Counts	5.77%

Assay Definition

Assay Description:

Assay Type: DPM (Single)
Report Name: Report1
Output Data Path: C:\Packard\Tricarb\Results\Default\99tc_dpm\20111005_1749\Replay_20111008_170016
Raw Results Path: C:\Packard\Tricarb\Results\Default\99tc_dpm\20111005_1749\20111005_1749.results
Assay File Name: C:\Packard\TriCarb\Assays\99tc_dpm.lsa

Count Conditions

Nuclide: 99tc
   Quench Indicator: tSIE/AEC
   External Std Terminator (sec): 10 sec
   Pre-Count Delay (min): 0.00
Quench Set:
   Low Energy: 99Tc
Count Time (min): 60.00
Count Mode: Normal
Assay Count Cycles: 1          Repeat Sample Count: 1
#Vials/Sample: 1               Calculate % Reference: Off

Background Subtract

Background Subtract: Off
Low CPM Threshold: Off
2 Sigma % Terminator: Off

Regions          LL       UL
A               0.0    292.0
B               0.0    292.0
C               0.0   2000.0

Count Corrections

Static Controller: On          Luminescence Correction: On
Colored Samples: On            Heterogeneity Monitor: Off
Coincidence Time (nsec): 18    Delay Before Burst (nsec): 75

LSC Bench Sheet

Tc-99

Client: Fluor-B&W Portsmouth
Task Order: 110825-10, 110915-9
Prep Page: 12-193
Prep Date: 4-Oct-11

Project #: 16526.05.00X
SRR: 45511, 45412
RL: 20 pCi/L
Units: L

TPU Factors	%
Aliquot Amount	2.00%
Standards	5.00%
Quench Curve	0.50%
Sub Sampling	2%
TPU of net Counts	**5.77%**

Sample Calculations

dpm = cpm / (eff-1 / 100) - avg bkg dpm

Activity pCi/g = dpm * DF / 2.22 (dpm to pCi)

TPU pCi/L =SQRT(Counting Error^2+ (systematic TPU% /100) ^2*Sample Activity^2)

MDC pCi/g = (4.65*SQRT((AVG(bkg cpm))/time)/((Eff / 100)*Sample Amt)/2.22+3/(Eff /100*Sample Amt* Time))/ 2.22

Counting Error = SQRT(cpm/time + bkg cpm/bkg time)/ Sample Amount / (Eff/100 * 2.22)

(RPD) = Abs Value(Sample-Duplicate) / ((Sample + Duplicate) / 2) * 100

Duplicate Evaluation = (Sample-Duplicate) / sqrt ((TPUsample^2) + (TPUdup^2)) ≤ 3

```

Assay Definition

Assay Description:

Assay Type: DPM (Single)
Report Name: Report1
Output Data Path: C:\Packard\Tricarb\Results\Default\99tc_dpm\20111012_1229
Raw Results Path: C:\Packard\Tricarb\Results\Default\99tc_dpm\20111012_1229\20111012_1229.results
Assay File Name: C:\Packard\TriCarb\Assays\99tc_dpm.lsa

Count Conditions

Nuclide: 99tc
  Quench Indicator: tSIE/AEC
  External Std Terminator (sec): 10 sec
  Pre-Count Delay (min): 0.00
Quench Set:
  Low Energy: 99Tc
Count Time (min): 60.00
Count Mode: Normal
Assay Count Cycles: 1   Repeat Sample Count: 1
#Vials/Sample: 1   Calculate % Reference: Off

Fluor B&W Portsmouth
16526.05.00K
TD# 110825-10, 110915-9
12-217
WAN
Day21

Background Subtract

Background Subtract: Off
Low CPM Threshold: Off
2 Sigma % Terminator: Off

Regions	LL	UL
A	0.0	292.0
B	0.0	292.0
C	0.0	2000.0

Count Corrections

Static Controller: On   Luminescence Correction: On
Colored Samples: On   Heterogeneity Monitor: Off
Coincidence Time (nsec): 18   Delay Before Burst (nsec): 75
