RE: Ohio EPA Concurrence of D3 Revised Remedial Investigation and Feasibility Study Report for the Site-Wide Waste Disposition Evaluation Project for the Portsmouth Gaseous Diffusion Plant, Including the Corrective Action Management Unit Supplement

Dear Ms. Wiehle and Mr. Bradburne:

Pursuant to the requirements in Section XV, Review of Submissions of *The April 13th, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification for the Portsmouth Gaseous Diffusion Plant (Decontamination and Decommissioning Project)* (hereinafter referred to as DFF&O), Ohio EPA is providing concurrence with the D3 Remedial Investigation and Feasibility Study Report for the Site Wide Waste Disposition Evaluation Project (RI/FS Report) for the Portsmouth Gaseous Diffusion Plant. Ohio EPA provided DOE with conditional concurrence with respect to the RI/FS Report and conditional approval with respect to the draft preliminary waste acceptance criteria (WAC) in April 2014. The conditional concurrence and conditional approval letter did not require modification to the D3 WD RI/FS Report for the Site-Wide Waste Disposition Evaluation Project; however, it included a list of items to address in order to satisfy the conditions noted. DOE has met the conditions as outlined by revising and re-submitting an agreed upon Applicable or Relevant and Appropriate Requirements (ARARs) table, agreeing that Appendix E of the D3 RI/FS Report be read in context with Section 2 of the RI/FS Report, and by pursuing two proposed corrective action management units (CAMU) in accordance with Ohio Administrative rules (OAC) 3745-57-72.

During meetings between DOE and Ohio EPA, DOE proposed drafting a supplement to the RI/FS Report to include CAMU and principle hazardous constituent (PHC) concepts, which directly influence the Waste Acceptance Criteria (WAC). Ohio EPA agreed with DOE's proposal. The RI/FS Report Supplement was submitted on October 21, 2014, as part of the D3 RI/FS Report for the Site-Wide Waste Disposition Evaluation Project and Ohio EPA hereby concurs with the RI/FS Report Supplement pursuant to the requirements in Section XV, of the DFF&O. Furthermore, the RI/FS Report Supplement is approved, including any portions of the RI/FS Report Supplement that are relied upon as part of the WAC. Ohio EPA will be providing public notice and will seek public comment on the proposed CAMU designations. Designation would occur at the Record of Decision stage.

Consistent with the terms of paragraph 79 of the DFF&O, Ohio EPA's concurrence and approval is for purposes of the DFF&O and does not impact any US DOE obligations under any existing permits, authorizations, and orders, including but not limited to the Ohio Consent Decree and the hazardous waste installation and operation permit. In the event of any conflict exists between the Waste Disposition RI/FS, including the final WAC, and the DFF&O, the provisions shall be construed, if possible, so that effect is given to both, however, if the conflict is irreconcilable, the provisions of the DFF&O shall prevail. See, RI/FS SOW.

As set forth in paragraph 9c of the DFF&O, in the event any portion of the Work requires a permit, license, or other authorization from Ohio EPA or any other state, federal or local government agency, Respondent shall submit applications in a timely manner and take all other actions necessary to obtain such permit, license, or other authorization. (See, DFF&O, ¶9c.)

If you have any questions regarding this correspondence, please do not hesitate to contact me at 740-380-5289 or maria.galanti@epa.ohio.gov.

Sincerely,

Maria Galanti

EXECUTIVE SUMMARY

The Ohio Environmental Protection Agency (Ohio EPA) and the U.S. Department of Energy (DOE) have entered into a formal agreement regarding the decision-making process for the decontamination and decommissioning (D&D) of the Portsmouth Gaseous Diffusion Plant (PORTS) and for the associated waste management. The terms of the agreement between Ohio EPA and DOE are contained in *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto* (DFF&O).

This document, *Remedial Investigation and Feasibility Study Report for the Site-Wide Waste Disposition Evaluation Project at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio*, presents the information necessary to select a Site-wide disposal alternative for the waste generated under the DFF&O and to receive community input on the alternatives under consideration. This decision is designed to coincide closely with another major DFF&O decision, the fate of the majority of buildings at PORTS, which is evaluated in *Remedial Investigation and Feasibility Study Report for the Process Buildings and Complex Facilities Decontamination and Decommissioning at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio*.

The information in the Site-wide Waste Disposition Evaluation Remedial Investigation/Feasibility Study supports three elements of decision making: (1) problem definition, (2) solution identification, and (3) solution evaluation.

Problem Definition. If no action is taken, no D&D or waste disposal would occur; therefore, the buildings at PORTS would degrade, collapse, and remain where they fall. Contamination now safely contained within the building structures and equipment would slowly release to the environment during building degradation. Contaminants such as radionuclides, polychlorinated biphenyls, and asbestos would be a future threat to users of the buildings or users of the media adjacent to the buildings at PORTS and to terrestrial species that are present at PORTS.

An estimated 1.47 million cy of building/structure waste are anticipated to be generated from demolishing the buildings at PORTS if D&D is selected as the remedial action. The vast majority of this waste would originate from the three large gaseous diffusion process buildings: X-326, X-330, and X-333. The waste volumes include the structure of each facility, all process and industrial equipment within each facility, facility slabs, and soil that would be generated incidental to removal of the facility slabs. The balance of the volume from a D&D decision would come from hundreds of smaller buildings and structures and is expected to be 0.35 million cy of waste or approximately 25 percent of the total PORTS D&D waste forecast.

The primary waste forms are presented in Table ES.1. These waste forms are the basis of calculations presented in Sections 8 and 9.

Table ES.1. Waste Volume Summary

D&D Waste Form Description	In Situ Volume (cy)
Residual Soil[a]	53,000
Building Waste	1,032,000
Process Gas Equipment	272,000
Targeted Recyclables	110,000
Total DFF&O Waste and Recyclables	**1,467,000**

[a] See paragraph 5.e. of the DFF&O for the definition of D&D.

D&D = decontamination and decommissioning
DFF&O = *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto*

Included in the 1.47 million cy of waste resulting from building demolition are an estimated 53,000 cy of residual soil, as described in the DFF&O, paragraph 5(e)(3) and 5(e)(4)(ii), which are anticipated to be generated during building demolition and foundation and subsurface structure removal that would require disposal. Additionally, the impacts and implications of up to an estimated 710,000 cy of Ohio Consent Decree contaminated soil (from deferred units) from the remaining environmental cleanup activities are considered, acknowledging that additional exemptions and/or authorizations would be necessary to excavate the waste and also to place any such waste in an on-Site disposal cell (OSDC). The 710,000 cy is an estimate established for the purposes of conducting a complete and thorough evaluation of the alternatives. The actual volume of any Ohio Consent Decree contaminated soil will be determined based on several factors. The decision to excavate and dispose of Ohio Consent Decree contaminated soil is not being made under this project. Placement of such Ohio Consent Decree contaminated soil would need to meet the requirements of the waste acceptance criteria (WAC) for the potential OSDC in order to be protective of human health and the environment.

Solution Identification. Three alternatives have been developed in the feasibility study. Alternative 1 is the no-action alternative, the basis to which the action alternatives are compared. Alternative 2 is the on-Site alternative (with appropriate off-Site disposal based on on-Site disposal WAC), and Alternative 3 is the off-Site alternative. Both action alternatives include opportunities for recycling and/or reuse of certain materials.

A number of potential OSDC locations across PORTS were studied and evaluated. From this evaluation, two areas, both of which are located above thick shale, were determined to be the most protective for use in developing an on-Site disposal alternative. However, one of the locations was determined to have preferable operational parameters and improved constructability, and thus was used as a representative location to develop the on-Site alternative.

Alternative 2 has a potential engineered disposal facility with a multi-layer liner, leachate collection and treatment system, and multi-layer cap. Any waste that could not meet the WAC would be treated or sent off-Site for disposal. The representative process options for the off-Site disposal elements of Alternative 2 and for all of Alternative 3 are Energy*Solutions* in Utah, a commercial facility that has previously received DOE waste, for mixed Resource Conservation and Recovery Act of 1976, as amended, or Toxic Substances Control Act of 1976 low-level (radioactive) waste (LLW); the DOE Nevada National Security Site in Nevada for LLW; and the Pike Sanitation Landfill in Pike County for construction and demolition debris as well as solid waste. Significant construction and operational challenges would be associated with an on-Site disposal alternative, but on-site disposal facilities have been built and successfully operated at several DOE facilities.

Alternative 3, off-Site disposal, assumes most of the waste would be sent by rail for off-Site disposal. Significant challenges would be associated with packaging and shipping some of the larger process equipment, but waste, including soil and process equipment, has been shipped across the United States from PORTS and other DOE facilities.

As previously noted, each action alternative includes a commitment by DOE to seek opportunities for the recycle and/or reuse of materials within the scope of the D&D effort for the gaseous diffusion plant. The final decision to recycle and/or reuse specific materials or discrete waste streams would be at the discretion of DOE so long as the recycle and/or reuse materials fits the definition of D&D, does not require modification of any Ohio EPA-approved or -concurred with Submissions (e.g., Proposed Plan, Decision Document, Remedial Design, etc.), and is in compliance with all applicable or relevant and appropriate requirements (ARARs). If DOE's recycling proposal requires modification of any regulatory documents (e.g., Proposed Plan, Decision Document, Remedial Design, etc.), DOE will submit its proposed modification to Ohio EPA for approval or concurrence, as applicable. For the purposes of evaluating the alternatives, approximately 110,000 cy of materials are tentatively identified from the scope of the D&D that may be candidates for recycle and/or reuse and are included in the analyses of each of the action-based remedial alternatives. The final identification of specific materials for recycle and/or reuse by DOE would take place during the follow-on remedial design and remedial action phases of the project.

Solution Evaluation. All of the alternatives were evaluated with respect to the DFF&O and Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended (CERCLA) criteria. The no-action alternative is not protective and does not meet threshold criteria. Both the on-Site and off-Site alternatives meet the threshold criteria of protectiveness and compliance with ARARs except that a waiver of the siting requirement in *Ohio Administrative Code* 3745-27-07(H)(4)(d) to not dispose of solid waste within 200 ft of a stream would be needed for the on-Site alternative. The waiver sought is discussed in more detail later in this document. Three key criteria differentiate the on-Site and off-Site alternatives: (1) transportation risk, (2) duration, and (3) cost.

In regard to transportation risk, estimated injuries from a transportation accident were calculated to be 8.8 for Alternative 2 (on-Site disposal), while the same transportation risk would be 18.7 injuries for Alternative 3 (off-Site disposal). The estimated numbers of potential fatalities associated with transportation efforts for Alternative 2 are considerably less than 1, and for Alternative 3 are approximately 2.4.

In regard to duration, Alternative 3 is estimated to take 50 percent longer to implement than Alternative 2. This is primarily due to the logistics of moving a large quantity of waste across the country via rail, which is more challenging than moving that amount of waste across PORTS. Second, with equivalent annual funding, the added costs of off-Site disposal would lengthen the schedule of Alternative 3 over that of Alternative 2.

The estimated present worth cost for Alternative 2 is $0.882 billion. The estimated present worth cost for Alternative 3 is $1.1 billion.

This report, after consideration of regulatory agency and community input, provides information for selection of a preferred alternative for disposition of waste resulting from D&D actions at PORTS. Other supporting documents and information considered during the CERCLA process are available to the public in the Administrative Record File for this project. This report will be followed by a Proposed Plan that presents the preferred alternative and solicits public input, and subsequently by a Record of Decision that documents the selected alternative and addresses public comments on the Proposed Plan.

1. INTRODUCTION

A total of 3,777 acres of federal land. An enriched uranium production mission that spanned 47 years (1954-2001). Three of the largest industrial buildings ever constructed—each with more than 30 acres of enriched uranium production capacity under roof. An enrichment system composed of 14,700 process components and 172 miles of internal nickel-plated pipelines. Four hundred and fifteen ancillary support buildings and structures that supported the enrichment mission within the interior 1,000-acre industrial area of the site. Five groundwater contamination plumes totaling 160 acres, each with interim measures and/or monitoring now in place. Thirteen legacy landfills—located in five general areas of the site and totaling 101 acres—that were compliantly closed under previous regulatory decisions. And, ultimately—once the final remaining facility decontamination and decommissioning (D&D) and affected environmental media cleanup decisions are made—the potential generation of upwards of 2 million cy of new demolition and environmental restoration wastes that will require safe and permanent disposal. The U.S. Department of Energy's (DOE's) Portsmouth Gaseous Diffusion Plant (PORTS) D&D Project, located in Pike County 4 miles south of the village of Piketon, Ohio, is arguably one of the largest and most complex environmental restoration projects underway in the nation today.

This Site-wide Waste Disposition Remedial Investigation/Feasibility Study (RI/FS) report provides technical support for one of the key remaining regulatory decisions driving the PORTS cleanup program: the decision as to where and how any wastes resulting from the D&D of the Portsmouth gaseous diffusion plant (GDP) buildings and structures at the Portsmouth reservation will be permanently dispositioned.

In April 2010, DOE and the Ohio Environmental Protection Agency (Ohio EPA) entered into a regulatory agreement for the PORTS federal facility. This agreement sets the stage for how the D&D and waste disposition decisions for PORTS will proceed. The agreement is known as *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto* (DFF&O) (Ohio EPA 2012a), adopts Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended (CERCLA) decision-making protocols as its underlying regulatory framework and decision-making architecture. Pursuant to Section I of the DFF&O, the DFF&Os were issued to DOE pursuant to the authority vested in the Director of Ohio EPA under Ohio Revised Code (ORC) Sections 3704.03, 3734.13, 3734.20, 6111.03, and 3745.01 and DOE entered into the DFF&O pursuant to Section 104 of CERCLA, 42 *United States Code* §9604, Executive Order (EO) 12580, and the Atomic Energy Act of 1954, as amended (AEA), 42 *United States Code* §2011, *et seq.*

Using a CERCLA framework, the DFF&O defines the steps for identifying a range of technical alternatives for the D&D and waste disposition components of the project, and reaching formal decisions on how best to proceed. The steps include developing viable alternatives; evaluating and comparing them; gaining public feedback on the range of alternatives; selecting a final approach and formalizing the decisions; and then defining the downstream regulatory requirements for successful implementation of the selected D&D and waste disposition remedial actions.

As a regulatory blueprint, the DFF&O envisions the following principal decision elements (termed in the DFF&O as "projects") as the means to carry out the remaining major GDP D&D and waste disposition decisions for PORTS:

- **The Process Buildings and Complex Facilities D&D Evaluation Project.** This remedial action project consists of the RI/FS, Proposed Plan, Record of Decision (ROD), and Remedial Design/Remedial Action (RD/RA) documents for most process-related PORTS structures, as identified in Attachment H of the DFF&O. The emphasis of this remedial action is to evaluate whether to D&D the buildings and structures, and comparatively examine the impacts if no D&D action is taken and the buildings are hypothetically allowed to degrade with no institutional or engineering controls in place.

- **Non-Time-Critical Removal Action Projects for Support Structures.** This decision-making option is recognized in the DFF&O to facilitate the D&D of various combinations of support structures (outside of the Process Buildings and Complex Facilities D&D Evaluation Project) as fast-track, schedule-driven subprojects. As non-time-critical removal actions, D&D of the support structures would be accomplished by identifying groups of structures and using Engineering Evaluation/Cost Analyses, Action Memoranda, and Removal Action Work Plans for the groups of structures identified. The support structures deemed acceptable in the DFF&O as removal action candidates are identified in Attachment G of the DFF&O.

- **The Site-wide Waste Disposition Evaluation Project.** This remedial action project is recognized in the DFF&O as the regulatory means to reach a remedial action decision for the dispositioning of the D&D wastes to be generated under the work activities contemplated by the DFF&O. Potential waste streams associated with environmental media cleanup activities to be conducted under the Resource Conservation and Recovery Act of 1976, as amended, (RCRA) Ohio Consent Decree and for which DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste streams in any potential on-Site disposal cell (OSDC) that might be constructed as a result of the Site-wide Waste Disposition Evaluation Project are acknowledged in the DFF&O as other potential waste streams. The Site-wide Waste Disposition Evaluation Project consists of the RI/FS, Proposed Plan, ROD, and RD/RA documents necessary to implement the selected remedial action.

1.1 PURPOSE OF THE REPORT

The purpose of this RI/FS report is to evaluate waste disposal alternatives to address wastes anticipated to be generated during the D&D of the Portsmouth GDP consistent with the scope of the DFF&O. Disposal options include the on-Site disposal of certain acceptable waste materials in a newly engineered and constructed waste disposal cell and off-Site disposal at properly permitted and/or licensed disposal and/or treatment facilities.

Waste not generated under the DFF&O are anticipated to be generated during the cleanup of the GDP. These waste streams will be generated pursuant to a different regulatory decision framework than the DFF&O. This RI/FS recognizes the possibility that this additional waste could be disposed in the potential OSDC, assuming the required authorizations are obtained, by separately analyzing the general impacts and implications attributed to the possible disposal of these non-D&D waste. This RI/FS does not provide Ohio EPA authorization for the excavation and disposal decisions for these other wastes. Nevertheless, DOE has evaluated the environmental impact, if any, of the excavation and disposal. DOE's analysis has determined that placement of this waste in the potential OSDC would be protective of human health and safety and the environment assuming such waste meets the waste acceptance criteria (WAC).

To clarify the regulatory authorities that apply to the various waste streams considered in this document, each waste stream discussed throughout the rest of the document is identified by a regulatory category (RC). Likewise, this document also discusses the form that the waste stream takes that is relevant to assumptions made about shipping and placement of the waste stream. To clarify which form the waste stream takes, each waste stream is also identified by an engineering category (EC). The RCs and the ECs are defined in Table 1.1. In the text, these categories are used when the waste being described is only a subset of all possible categories. If the regulatory type of waste is not relevant to the discussion, only the ECs are used. Likewise, if the EC is not relevant to the discussion, only the RCs are used.

Table 1.1. Regulatory and Engineering Categories of PORTS Wastes/Materials

Category	Definition
Regulatory Categories	
RC-1	DFF&O waste including building D&D waste and residual soil as defined in the DFF&O.
RC-2	Ohio Consent Decree waste.
RC-3	Non-DFF&O, Non-Ohio Consent Decree waste composed of previously interred waste in closed waste management units.
RC-4	Other waste for which DOE is a responsible party, including but not limited to CERCLA actions that are not addressed within RC-1, RC-2 or RC-3.
Engineering Categories	
EC-1	Soil and soil-like materials or wastes.
EC-2	Non-soil like, non-liquid waste that generally require EC-1 materials or wastes to achieve compaction requirements for placement in the potential OSDC.

CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended
D&D = decontamination and decommissioning
DFF&O = *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto*
DOE = U.S. Department of Energy
EC = engineering category
OSDC = on-Site disposal cell
RC = regulatory category

Whenever excavation and/or disposal of non-D&D waste (Categories RC-2, RC-3, or RC-4) is discussed in this document, whether in terms of additional waste material or fill, it is to be understood that additional authorization/approval would be required to undertake this activity.

DOE combined the RI and FS reports into a comprehensive RI/FS report, rather than issuing stand-alone individual RI and FS reports initially contemplated by the DFF&O. As a combined RI/FS report, the document accomplishes three integrated objectives: (1) it defines the magnitude of the waste disposal problem, (2) it defines the range of potential solutions, and (3) it individually and comparatively evaluates the potential solutions so a preferred approach presented by DOE can be evaluated by regulatory agency decision makers and be shared with the public for review and comment through a subsequent Proposed Plan.

1.1.1 Scope and Role of the Site-wide Waste Disposition Decision

The scope of the Site-wide waste disposition decision is to determine the best overall approach, based on the regulatory required evaluation criteria, to permanently dispose of the waste to be generated from the D&D of the Portsmouth GDP within the scope of the DFF&O. This document also discusses other possible anticipated waste streams, which are not D&D and for which separate authorization would be needed to excavate and place such waste into a potential OSDC.

1.1.1.1 Scope of Site-wide waste disposition decision

The scope of the decision has several facets. The DFF&O and CERCLA's required nine criteria are used to conduct the technical-, risk-, and cost-based balancing evaluation of various alternatives to address the following facets of the decision. An evaluation of National Environmental Policy Act of 1969 (NEPA) values is included. The decision will also identify the regulatory requirements for design and/or planning implementation of the selected remedial action, using the applicable or relevant and appropriate requirements (ARARs).

Disposal

Ultimately, the waste disposition evaluation will support a decision between off-Site disposal and on-Site with some off-Site disposal for the waste volumes generated during the remediation efforts conducted under the DFF&O (RC-1). A range of alternatives is developed in this RI/FS to evaluate the disposal alternatives.

Recycle and/or Reuse

DOE is committed to recycling and/or reuse of materials from the PORTS D&D Project regardless of the selected disposal remedy. Recycling and/or reuse is part of each disposal alternative. Specific recycle and/or reuse decisions will be made for discrete materials and waste streams across all phases of the D&D project as appropriate, including during performance of the RI/FS, remedial design, and remedial actions. Decisions to recycle and/or reuse materials will be made at DOE's discretion, following an evaluation of relevant factors and considerations, so long as the recycle and/or reuse materials fits the definition of D&D, does not require modification of any Ohio EPA-approved or -concurred with Submissions (e.g., Proposed Plan, Decision Document, Remedial Design, etc.), and is in compliance with all ARARs. If DOE's recycling proposal requires modification of any regulatory documents (e.g., Proposed Plan, Decision Document, Remedial Design, etc.), DOE will submit its proposed modification to Ohio EPA for approval or concurrence, as applicable.

Fill Sources to Support Development of an On-Site Disposal Alternative

To control subsidence in a disposal cell, fill is co-disposed with large quantities of waste from building demolition (EC-2). Fill is always designated as having soil-like properties and therefore is categorized as EC-1. To completely evaluate an on-Site disposal alternative, it is necessary to consider the source of fill that would be used in the operation of a potential OSDC, should that alternative be selected for implementation. This RI/FS evaluates a range of options for obtaining that fill. Purchasing fill or developing on-PORTS borrow areas are evaluated as potential sources as part of any disposal alternative that contains a potential OSDC. DOE anticipates that some non-D&D contaminated soil (RC-2, RC-3, EC-1) may be appropriate to use as fill. Any fill, regardless of source, would need to meet certain performance standards, which will be set forth in more detail in the Remedial Design documentation. The decision to use non-D&D contaminated soil (RC-2, RC-3, EC-1) for fill in the potential OSDC is evaluated in this document; however, additional regulatory approval would be required to excavate and dispose of this fill. Accordingly, DOE would seek exemptions and authorizations under Ohio laws and regulations to allow placement of such non-D&D contaminated soil (RC-2, RC-3, EC-1) streams in any potential OSDC. The impacts and implications of disposing of non-D&D contaminated soil (RC-2, RC-3, EC-1) from the remaining environmental cleanup activities in such a potential OSDC are considered in order to better inform design criteria and the WAC. DOE has determined that fill from any contaminated borrow areas would be protective of human health, safety, and the environment if it meets the WAC for the potential OSDC. Whenever the use of non-D&D contaminated soil (RC-2, RC-3, EC-1) as fill is discussed in this document, it is to be understood that DOE would need to seek additional regulatory approval for excavation and placement in the potential OSDC.

Ohio Consent Decree and 1997 Administrative Consent Order Waste
There is the potential for generation of waste streams associated with environmental media cleanup activities to be conducted under the Ohio Consent Decree and the 1997 Administrative Consent Order (RC-2, EC-1). DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste streams in any potential OSDC that might be constructed as a result of the Site-wide Waste Disposition Evaluation Project. The impacts and implications of disposing of the waste (RC-2, EC-1) from the remaining environmental cleanup activities in such a potential OSDC are considered in order to better inform design criteria and the WAC.

This RI/FS does not provide the necessary authorization for the excavation and disposal decisions for the waste from other environmental cleanup activities conducted under the Ohio Consent Decree (RC-2, EC-1). Nevertheless, DOE has evaluated the potential environmental impact of the disposal of this waste stream and has determined that placement of this waste in the potential OSDC would be protective of human health, safety, and the environment assuming such waste meets the WAC. Whenever excavation and/or disposal of this non-D&D waste (RC-2, EC-1) is discussed in this document, it is to be understood that additional authorization/approval would be required to undertake that activity.

1.1.1.2 Role of Site-wide waste disposition decision

Ohio EPA entered the orders pursuant to the authority vested in the Director of Ohio EPA under the various ORC Sections while DOE entered these Orders pursuant to Section 104 of CERCLA, among others. The DFF&O uses CERCLA decision-making protocols as its underlying regulatory framework and decision-making architecture. RI/FSs conducted under CERCLA have some special considerations. To develop objectives and goals of remediation and to develop alternatives, the requirements of federal and state regulations that apply or are relevant and appropriate (called ARARs) to the problem at hand must be identified and understood. Entirely on-Site remedial actions are required to attain ARARs, unless specific ARARs are waived in accordance with CERCLA. For entirely on-Site remedial actions, the ARARs include only the substantive requirements of federal, state, and local environmental or facility siting laws/regulations; they do not include occupational safety or worker radiation protection requirements or administrative requirements of the laws/regulations. Additionally, per the DFF&O and 40 *Code of Federal Regulations* (*CFR*) 300.400(g)(3), substantive requirements of other advisories, criteria, or guidance that are not ARARs may be considered in determining remedies (to-be-considered [TBC] guidance). For actions that occur off Site, all elements of the laws and regulations, including the administrative requirements, must be met.

Another consideration of developing and evaluating alternatives under CERCLA is the concept of representative process options. As discussed in Section 4.2.5 of the U.S. Environmental Protection Agency's (EPA's) 1988 Guidance for Conducting RI/FSs (EPA 1988), during the development of alternatives phase of an RI/FS, "…technology processes (called process options) considered to be implementable are evaluated in greater detail before selecting one process to represent each technology type to simplify the subsequent development and evaluation of alternatives without limiting flexibility during remedial design. The representative process provides a basis for developing performance specifications during preliminary design; however, the specific process actually used to implement the remedial action at a site may not be selected until the remedial design phase." For example, an existing off-PORTS commercial disposal facility has been selected as a representative process option for off-Site disposal of mixed low-level (radioactive) waste (MLLW). This selection allows detailed cost estimates and estimates of transportation risk to be generated while still allowing more detailed evaluations to be used to conduct the final selection. However, identifying this facility as a representative facility during this RI/FS does not mean that DOE has selected it as the disposal facility for implementation. In the event off-Site disposal is a component of the final remedy selected in the ROD, DOE will be able to consider and use all viable, regulatory-compliant off-PORTS disposal locations for MLLW disposal that are available.

1.1.2 Relationship to Other Documents

The RI/FS report is a document required by the DFF&O. It provides detailed technical documentation and foundational engineering and scientific information to support a remedial action decision. It is made available for use by the general public through the Site-wide Waste Disposition Administrative Record File. Three other documents will be issued after Ohio EPA concurs with the RI/FS report:

- The Proposed Plan, which summarizes the results of the RI/FS at a level of detail that supports review by the general public and other entities such as state agencies that may elect to provide input to the decision. The Proposed Plan also identifies DOE's preferred remedial action for official comment during the formal public comment period.

- The ROD, which memorializes the final remedial action decision for the DFF&O D&D work activities.

- The Responsiveness Summary, which provides DOE's formal responses to comments received on the Proposed Plan during the formal public comment period. The Responsiveness Summary will be attached to the ROD and placed in the official Administrative Record for this remedial action.

Together the RI/FS report, Proposed Plan, ROD, and Responsiveness Summary comprise the decision-making documents leading to selection of the preferred remedial action. Other implementation documentation, such as the RD/RA Work Plan and other required remedial design or planning document submittals, will follow formal issuance of the ROD. The implementation documents will also be subject to Ohio EPA review and approval/concurrence, as applicable, under the requirements of the DFF&O.

This RI/FS report was prepared in accordance with the DFF&O requirements. The general approach to evaluating potential remedial actions is based on EPA guidance (EPA 1988). The RI/FS approach also incorporates NEPA values in accordance with the DOE Secretarial Policy on NEPA (DOE 1994). While NEPA values are incorporated throughout this RI/FS, they are the particular focus of certain sections in this report. The affected environment is described in Section 3, Physical Characteristics of the Study Area, and the environmental consequences (direct and indirect impacts and mitigation measures) are described in Section 9, Detailed Analysis of Alternatives.

1.1.3 Relationship to Other Environmental Restoration Activities at PORTS

The DFF&O decisions for process facility and support structure D&D and Site-wide waste disposition remedial actions are part of a larger environmental remediation effort that has been underway at PORTS since the late 1980s. Most notably, the earlier Ohio Consent Decree efforts focused on interim soil and groundwater restoration needs outside of the main processing area boundaries. Earlier efforts also focused on regulatory closure of the existing 101 acres of historical landfills at PORTS.

The DFF&O adopts a CERCLA-based decision framework to complete decision making for the remaining D&D and D&D waste disposition decisions at PORTS. The earlier Ohio Consent Decree soil and groundwater and landfill closure efforts were conducted under the RCRA corrective action program obligations in accordance with the Facility's Ohio Consent Decree.

Beyond the DFF&O decisions, several key environmental restoration decisions remain, which will be accomplished under the Ohio Consent Decree: (1) establishment of final cleanup levels for soil and closeout of the remaining RCRA solid waste management units (SWMUs) that were deferred for cleanup until the process facility D&D decision is made and (2) selection of final remedial actions for affected groundwater within the reservation to complete the interim actions now in place. In addition, there may be the need for other actions, including but not limited to those under CERCLA, to be conducted (RC-4).

Section 1.2.2.2 provides an overview of the regulatory and environmental restoration history at PORTS, dating back to 1989.

1.2 SITE BACKGROUND

This section provides a description of the PORTS Facility and a history of the PORTS operations, including the production mission history and the historical environmental restoration and regulatory compliance activities.

1.2.1 Site Description

PORTS, which began operations in 1954, is located on a 3,777-acre federal reservation in a rural area of Pike County, Ohio (Figure 1.1). From 1954 until 2001, the PORTS gaseous diffusion process enriched uranium for DOE and predecessor agencies, the Naval Nuclear Propulsion Program, and commercial customers. In 1993, DOE began leasing the uranium enrichment production and operations facilities at PORTS for commercial enrichment to the United States Enrichment Corporation (USEC). Uranium was enriched at PORTS by USEC until May 2001, at which time the production facilities were placed into a cold-standby mode. During cold standby, the process buildings were maintained with a restart capability as a strategic hedge against a disruption in the nation’s supply of enriched uranium. DOE terminated the cold-standby program in September 2005 and replaced it with a cold-shutdown program, which no longer maintained the gaseous diffusion restart capability. The process buildings, support facilities, and auxiliary facilities are more than 50 years old but have been maintained in a “safe and secure” condition. If demolition of the gaseous diffusion buildings and ancillary structures and systems is selected as the preferred alternative for the buildings, a significant amount of waste will be generated and will require disposal. The disposal alternatives for this potential waste are being evaluated in this waste disposition RI/FS.

The GDP and surrounding area are owned by DOE. The plant consists of 415 facilities (“facility” can mean a building, utility system, or infrastructure unit) with three main process buildings known as X-333, X-330, and X-326, which house the gaseous diffusion equipment. Various support and auxiliary buildings/structures include many substantial buildings/structures for product feed and transfer operations, maintenance, steam generation, chemical cleaning, decontamination, process heat removal, water supply, water storage, water distribution, and electrical power distribution. Other buildings house the administrative offices, hospital, cafeteria, security headquarters, plant control facility, and laboratory support. These buildings consist mostly of concrete/steel construction on concrete slabs.

The three process buildings, as well as most of the remaining buildings and structures, are situated within the approximately 1,000-acre industrialized area that lies within Perimeter Road. The industrialized area includes a 750-acre controlled access area. The central, industrialized area is largely devoid of trees, with managed lawns, parking lots, and paved roadways dominating the open space. The portion of the DOE property outside of Perimeter Road, consisting of more than 2,500 acres, is used for a variety of purposes, including a water treatment plant, sediment ponds, sanitary and inert landfills, cylinder storage yards, open fields, and forested buffer areas (U.S. Nuclear Regulatory Commission [NRC] 2006a). Closed existing landfills and burial grounds account for approximately 101 acres.

Figure 1.1. PORTS Location

Natural uranium, as mined, contains approximately 99.3 percent of the nonfissionable uranium-238 isotope and approximately 0.7 percent of the fissionable uranium-235 isotope. Based on the very small difference in molecular weight between these two isotopes, isolation of these isotopes is achieved using a physical separation process. The gaseous diffusion process uses uranium hexafluoride (UF_6), the only compound of uranium that exists as a gas at reasonable temperatures and pressures, as the feed stock. This gas is forced through a porous medium, or “barrier.” Gaseous diffusion is similar to the distillation process because the light weight components (uranium-235) move up through the process equipment and are removed near the top, and the heavier components (uranium-238) move down and are removed near the bottom.

During the uranium enrichment process at PORTS, uranium-235 moved through the barriers more easily, increasing in concentration as it moved through the process. About half of the gas diffused through the barrier was fed to the next higher stage, while the remaining undiffused portion was recycled to the next lower stage. The uranium enrichment process was initiated in X-333 and continued in series to X-330 and X-326. The “products” from the enrichment operations, highly-enriched uranium (HEU) (greater than 90 percent uranium-235), intermediate-enriched uranium (between 5 and 90 percent uranium-235), and low-enriched uranium (LEU) (less than or equal to 5 percent uranium-235), were withdrawn from X-326.

The basic separation equipment for gaseous diffusion is a “stage.” At PORTS, a stage consists of the following:

- A converter that contains porous separation media (referred to as the barrier material or barrier tubes) with the support structure to hold the separation media
- A gas cooler
- A compressor driven by an electric motor to move the UF_6 gas through the converter
- Interconnecting piping and control valves to contain and control the gas flows.

There are 4,080 stages at PORTS. The three process buildings were constructed to house the equipment and operations for uranium enrichment, collectively referred to as the “cascade.” The buildings are located in the center of the PORTS Facility and cover a combined footprint of approximately 90 acres under roof (Figure 1.2). A brief description of each process building is presented below.

X-333 Building

The X-333 Building was used for the initial enrichment of uranium (up to approximately 2 percent uranium-235 enrichment). The building is 1,456 ft long, 970 ft wide, and 82 ft high, with a combined floor space of 65 acres (two stories). This two-story, steel-frame structure is constructed of asbestos-containing transite siding and steel-reinforced concrete floors and columns. It has a flat, composite, built-up, tar and gravel-coated roof. Open truck alleys for rail and truck access are located on the east and west sides of the building.

The process equipment and its associated valves and piping are located on the second floor. This building contains eight units (80 cells and 640 stages) of ‘000’ equipment, which is the largest gaseous diffusion equipment at PORTS. The converters in the X-333 Building are approximately 13 ft diameter and 24 ft long, and weigh approximately 66,000 lb.

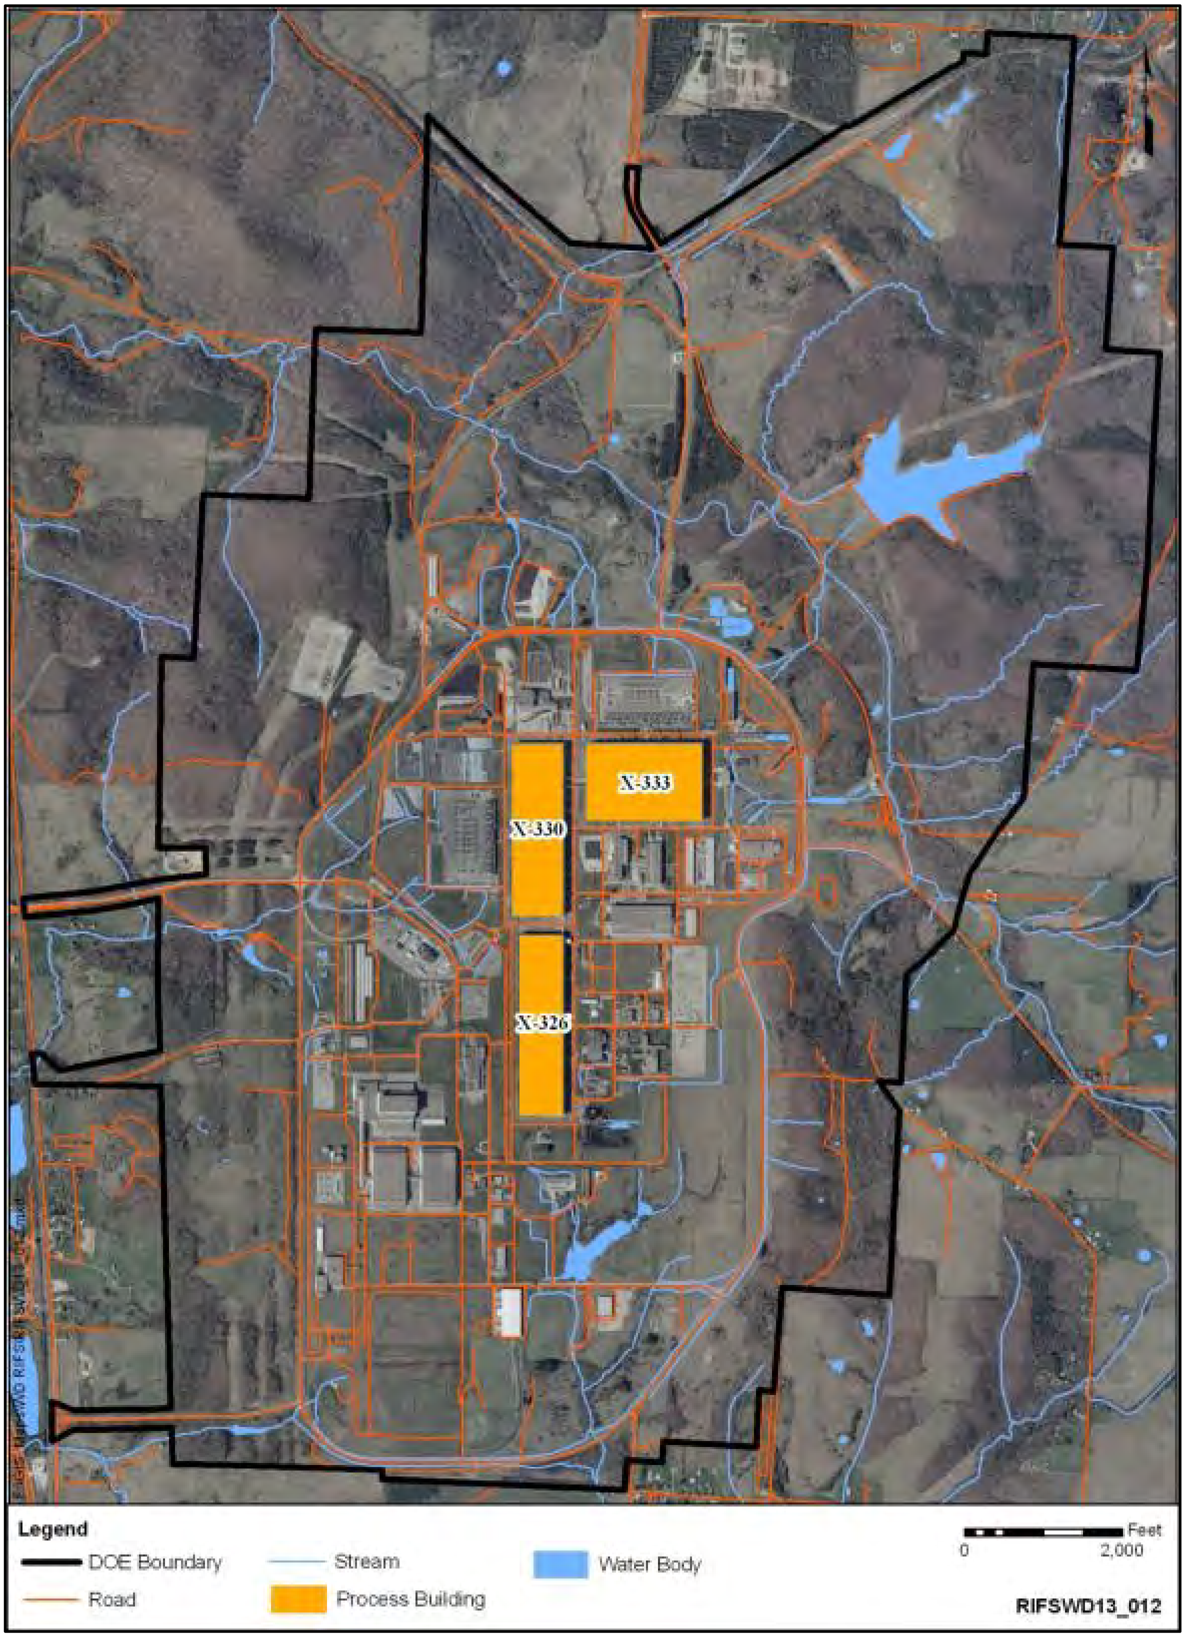

Figure 1.2. PORTS Facility

X-330 Building

The X-330 Building was used for the intermediate phase of uranium enrichment and tails withdrawal. This building is 2,176 ft long, 640 ft wide, and 66 ft high, and it has a combined floor space of 55 acres. The building construction is similar to that of the X-333 Building, with a two-story steel frame; asbestos-containing transite siding; steel-reinforced concrete floors and columns; and a flat, composite, built-up, tar and gravel-coated roof. The X-330 Building has one truck alley on its west side.

Similar to the X-333 Building, the process equipment and its associated valves and piping are located on the second floor. The X-330 Building is similar in design to the X-333 Building, but it contains two sizes of process equipment, ‘00’ (or X-31) and ‘0’ (or X-29), both smaller in size than the equipment in the X-333 Building. The X-330 Building contains six units of ‘0’ size equipment (60 cells and 600 stages) and five units of ‘00’ size equipment (50 cells and 500 stages).

X-326 Building

The X-326 Building was used for the high uranium enrichment phase and enriched product withdrawal. About two-thirds of the building was used to produce commercial grade nuclear material. This building is 2,280 ft long, 552 ft wide, and 62 ft high, and it has a combined floor space of 58 acres. The two-story steel-frame structure is constructed of asbestos-containing transite siding and steel-reinforced concrete floors and columns. In addition, this building has a flat, composite, built-up, tar and gravel-coated roof. The process equipment and its associated valves and piping are located on the second floor.

The X-326 Building contains two sizes of equipment, which are the smallest pieces of gaseous diffusion equipment at PORTS. The two sizes of process equipment are referred to as the X-27 size, the larger of the two sizes, and X-25 size, the smaller of the two sizes. The converters weigh 3,500 lb and 4,600 lb, respectively. There are three units of X-27-size equipment (60 cells and 720 stages) and 6.5 units of X-25-size equipment (130 cells and 1,560 stages). In addition, there are 10 six-stage cells, called “purge cells,” of X-25-size equipment specially designed to remove light gases from the UF_6 stream.

1.2.2 Site History

The sections below summarize the PORTS nearly 60-year history for two categorical areas. Section 1.2.2.1 focuses on the production mission history dating back to 1954 when PORTS began operations, and Section 1.2.2.2 focuses on the environmental restoration and regulatory compliance history dating back to 1989, when the Ohio Consent Decree was issued. This decree requires investigation and remediation of solid and hazardous waste units at PORTS in accordance with RCRA.

1.2.2.1 PORTS production and waste management history

PORTS began operations in 1954 and was one of three uranium enrichment facilities originally constructed in the United States; the other two were constructed in Oak Ridge, Tennessee, and Paducah, Kentucky. PORTS used the gaseous diffusion process to provide HEU to the U.S. Navy and LEU for electrical power generation. From 1991 until production ceased in 2001, PORTS produced only LEU for commercial power plants. In 1993, DOE leased the commercial uranium enrichment operations to USEC while retaining responsibility for certain environmental restoration and waste management activities, uranium programs, and long-term stewardship of non-leased facilities at PORTS.

In August 2000, USEC made a business decision to terminate its enrichment operations at PORTS and ceased those activities in May 2001. At that time, DOE contracted with USEC to establish a cold-standby program to maintain enrichment restart capability at the facility as a strategic hedge against disruption in the nation’s supply of enriched uranium. The cold-standby program was terminated by DOE at the end of fiscal year (FY) 2005, and the facilities have been maintained in cold-shutdown status while D&D was being planned.

Many operations and maintenance activities at PORTS involved hazardous conditions and the potential for exposure of personnel and the environment to radioactive and chemical hazards as hazardous substances. Enrichment process facilities with the potential for such exposures included the gaseous diffusion cascade and other process buildings; a process feed manufacturing plant; an oxide conversion plant; decontamination, cleaning, and uranium recovery operations; a smelter; and incinerators. Leaks and off-gassing from process equipment or components being repaired or replaced exposed workers and the environment to airborne uranium, transuranic constituents, fission products, fluorine, and hydrogen fluoride (HF) gas (DOE 2000a). Others worked with various hazardous substances such as asbestos, beryllium, lead, trichloroethene (TCE) and other solvents, polychlorinated biphenyls (PCBs), acids, chromium, nickel, lithium, and mercury. Radioactive materials and other hazardous substances were spilled or released to the environment from production-related facilities and attendant work activities.

Activities to manage wastes and liquid process effluents evolved over the operating lifetime of PORTS. Throughout the plant's history, efforts were made to minimize the loss of valuable enriched uranium in PORTS waste streams. However, in the early days of operation, on-PORTS sanitary landfills likely received some contaminated material because waste segregation practices were not fully implemented. As new requirements were enacted, additional waste streams, such as hazardous wastes, were restricted from disposal in on-PORTS landfills. Oils contaminated with PCBs and uranium were disposed of in oil biodegradation plots, burned in open containers, or incinerated (DOE 2000a).

The environmental monitoring program at PORTS was initiated in the 1970s in response to many of the new federal environmental regulations. In the 1970s, several new wastewater treatment systems were constructed to meet new permit requirements and to significantly reduce the levels of radionuclide emissions to surface water. The PORTS National Pollutant Discharge Elimination System (NPDES) permit, issued by the State of Ohio in the 1970s, required testing and reporting of specific chemical and physical properties and set limits on chemical discharges. Despite the discharge restrictions, legacy environmental contamination exists in ponds, local ditches, and streams (DOE 2000a).

In 1975, technetium-99 contamination was discovered in liquid effluents from X-705 (DOE 2000a). The technetium-99 was mainly discharged to Little Beaver Creek via the NPDES outfall associated with the X-701B Holding Pond. Some technetium-99 was released to the Scioto River. Technetium was also detected in some airborne discharges. The releases were documented in the Annual Site Environmental Reports. This discovery triggered significant, long-term efforts at PORTS to isolate sources of technetium contamination, develop or improve control methods, and establish appropriate monitoring protocols.

1.2.2.2 PORTS environmental restoration and regulatory compliance history

Dating back to 1989, eight major environmental regulatory documents have been established for PORTS, along with associated amendments. These are summarized in Table 1.2. The table identifies the document, its year of enactment, and its major intended purpose.

Table 1.2. PORTS Regulatory Documents

Regulatory Document	Date	Purpose
Ohio EPA Consent Decree	1989	Requires investigation and remediation of solid and hazardous waste units in accordance with RCRA, between Ohio EPA and DOE.
Toxic Substances Control Act Compliance Agreement (EPA and DOE)	1992	Brings DOE into compliance with TSCA regulations; and establishes D&D milestones for TSCA waste, as modified in 1997.
Ohio Hazardous Waste Facility Installation and Operation Permit (and Renewal)	1995-present	Allows RCRA-permitted container storage for hazardous waste with DOE as the Owner and Co-Operator and current Co-Operator; references the RCRA Corrective Action Orders: Ohio Consent, Administrative Consent Order, and Ohio Director’s Final Findings and Orders for Integration; and amended in 2011 to add/remove Co-operator.
Ohio Director’s Final Findings and Orders for Site Treatment Plan	1995	Allows for the storage of mixed hazardous waste beyond the 1-year regulatory limit; requires an Annual Site Treatment Plan Report; and the 1993 amendment was superseded.
Administrative Consent Order	1997	Requires investigation and remediation of solid and hazardous waste units in accordance with RCRA and CERCLA, between EPA and DOE.
Ohio Director’s Final Findings and Orders for Integration	1999	Integrates five RCRA closures into the RCRA Corrective Action Program. Provided for integration of groundwater monitoring and surveillance; maintenance of RCRA and solid waste units; amended in 2011 to update regulatory citations and include the D&D contractor.
Ohio Director’s Final Findings and Orders [for Depleted Uranium Hexafluoride]	2008	Requires DOE and assigned parties to generate and comply with the Depleted Uranium Hexafluoride Management Plan; amended in 2011 to add/remove assigned parties; and the 2004 and 2005 amendments were superseded.
Ohio Director’s Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action [for the Portsmouth Gaseous Diffusion Plant (Decontamination and Decommissioning Project)]	2010	Provides the framework for DOE to address the D&D of the GDP and support facilities using the CERCLA process; amended in 2011 with revisions to Attachments G, H, and I, corrected inadvertent omissions, reflected current strategy of documentation; and amended in 2012 with a revision to Attachment H.

CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (as amended)
D&D = decontamination and decommissioning
DOE = U.S. Department of Energy
EPA = U.S. Environmental Protection Agency
GDP = gaseous diffusion plant
Ohio EPA = Ohio Environmental Protection Agency
RCRA = Resource Conservation and Recovery Act, as amended
TSCA = Toxic Substances Control Act of 1976

The existing Ohio EPA Consent Decree, signed in August 1989 by Ohio EPA and DOE, requires DOE to complete investigations to determine the nature and extent of any environmental contamination that exists at PORTS, complete cleanup alternative studies, and implement corrective actions as needed.

Coincident with the Ohio EPA Consent Decree, DOE established the Environmental Restoration Program in 1989 to identify, control, and remediate environmental contamination at PORTS. The Environmental Restoration Program addresses inactive sites through remedial action, and it deals with contaminated soil and groundwater associated with active facilities. Because PORTS is a fairly large area, it was divided into four quadrants to facilitate the environmental contamination investigation and cleanup process. The Environmental Restoration Program was established and is currently operated to fulfill the cleanup requirements of the Ohio EPA Consent Decree and the Administrative Consent Order (known as the "Three Party Order") signed in June 1997.

DOE has completed the description of current environmental conditions, RCRA facility investigations (RFIs), and a cleanup alternatives study/corrective measures study for each quadrant. These investigations and reports detail the characteristics of PORTS that are pertinent to the waste disposition evaluation and characterized the nature and extent of contamination at PORTS. The primary sources of information include the RFIs for the four quadrants (DOE 1996a, 1996b, 1996c, 1996d) and the corresponding corrective measures studies (DOE 1998a, 1998b, 2000b, 2001a).

As a result of these studies, the focus has been to control contaminant migration and to address corrective action or closure of waste units that resided outside the main operating plant area.

1.2.2.3 Site-wide Waste Disposition Evaluation Project DFF&O history

A Pre-investigation Evaluation Report (PER) was prepared under the DFF&O and submitted to the Ohio EPA in October 2010 (DOE 2010a). The purpose of the PER was to identify the technical approach to be used in the waste disposition RI/FS, document the RI/FS scoping tasks, record the results from performing these tasks, and establish a framework for development of the waste disposition RI/FS Work Plan (DOE 2012a).

The waste disposition RI/FS Work Plan discussed the data gaps identified during the scoping, described the types of data needed to fill them, and proposed methods for collecting the data. These new data and already existing data were the necessary basis for developing waste disposal alternatives during the RI/FS. In addition, the work plan presented preliminary WAC for use in facility siting evaluations and determining the approach to calculating final WAC, if the on-Site disposal alternative were selected. WAC establish concentration and activity limits that ensure protection of human health and the environment. To further support the development of alternatives, the work plan provided a summary of the screening process used to identify potential locations for an on-Site waste disposal cell.

Filling these data gaps required the collection and analysis of numerous contaminant, geochemical, and geotechnical samples as well as waste characterization samples. Sampling and analysis plans (SAPs) were prepared to set forth the sampling approaches and protocols to be followed during RI/FS field activities and characterization of the process gas systems in support of alternatives associated with the Site-wide Waste Disposition Evaluation Project (DOE 2012a, 2011a). The RI/FS field activities SAP addressed data gaps related to siting a potential OSDC, and it also laid plans for collecting the hydrogeologic information necessary for developing modeled WAC. The equipment characterization SAP identified intrusive samples, nonintrusive samples, and measurements necessary to characterize the PORTS process gas systems and components. The analytical data from these samples and the measurements support estimating assumptions for waste materials and help to determine the quantities of waste to be disposed, and also support the development and evaluation of the alternatives.

1.3 REPORT ORGANIZATION

This RI/FS report consists of an executive summary, 10 individual sections constituting the main report, and 12 supporting appendices (Appendices A through L). A brief overview of each of the 10 sections contained in the main report is provided below. The overview includes a discussion of the content of the section, identifies the supporting appendices, and provides a summary of conclusions when appropriate. Readers should note that while the DFF&O contains outlines of required elements for individual RI and

FS reports, DOE has merged the two outlines into a combined RI/FS report. This report follows the combined outline and includes all of the required elements.

Figure 1.3 presents a summary flow diagram showing the CERCLA contents of the RI/FS report by section. Section 10 is not included as it was outside the CERCLA process. This figure will be used throughout the report to remind the reader of where he/she is in the document and what issues are addressed by a given section.

Section 1 – Introduction
Section 1 presents an overview of PORTS and its remediation history, discusses Facility-wide regulatory issues, defines the scope of the Site-wide waste disposition evaluation, and identifies the later decision documents that will be supported by the RI/FS.

Section 2 – Study Area Investigation
Section 2 provides a compilation of the field investigations performed to support the waste disposition evaluation. It summarizes relevant historical investigations, recent field investigations conducted during the RI/FS, and the results from these investigations. This section identifies the specific studies that were conducted to refine decision parameters and support technical evaluation of the alternatives under consideration in the FS.

In support of Section 2, Appendix A presents contamination characterization sample results, Appendix B presents boring and well installation logs, and Appendix C identifies the results from geotechnical and geochemical samples.

Section 3 – Physical Characteristics of the Study Area
Section 3 describes the existing environmental setting of PORTS and surrounding areas to support the FS. This information includes surface features, meteorology, surface water hydrology, geology, soils, hydrogeology, demography and land use, cultural resources, transportation, and ecology. The section is intended to support the identification of environmental pathways and receptors, which are used in development of the RI/FS conceptual site model (CSM). The CSM is a tool used in the human health and ecological risk evaluation and in the identification and development of protective and compliant remedial action alternatives.

To support Section 3, Appendix D identifies the characteristics of the final candidate locations for a potential OSDC under an on-Site disposal alternative.

Section 4 – Basis for Projected Waste Streams and Volumes and Potential Uncertainties
Section 4 presents updated estimates of D&D (RC-1) and environmental remediation waste volumes (RC-2, EC-1) that are anticipated to be generated at PORTS, and an assessment of the expected characteristics of the waste. This section also provides a discussion of the potential uncertainties associated with the waste volumes and characteristics.

The intent of this section is to support a waste disposition evaluation for future wastes generated under the DFF&O cleanup D&D work activities (RC-1) and to ensure any OSDC design and WAC takes into account these waste types. Additionally, DOE is evaluating non-D&D wastes (RC-2, EC-1) for potential placement in a potential OSDC, again to ensure the potential OSDC design and WAC can accommodate such waste streams if they are approved for placement in a potential OSDC. A discussion of potential fill sources (RC-2, RC-3) for any on-Site disposal options is also provided. This section concludes that sufficient information is available to adequately define waste volumes and characteristics for alternative

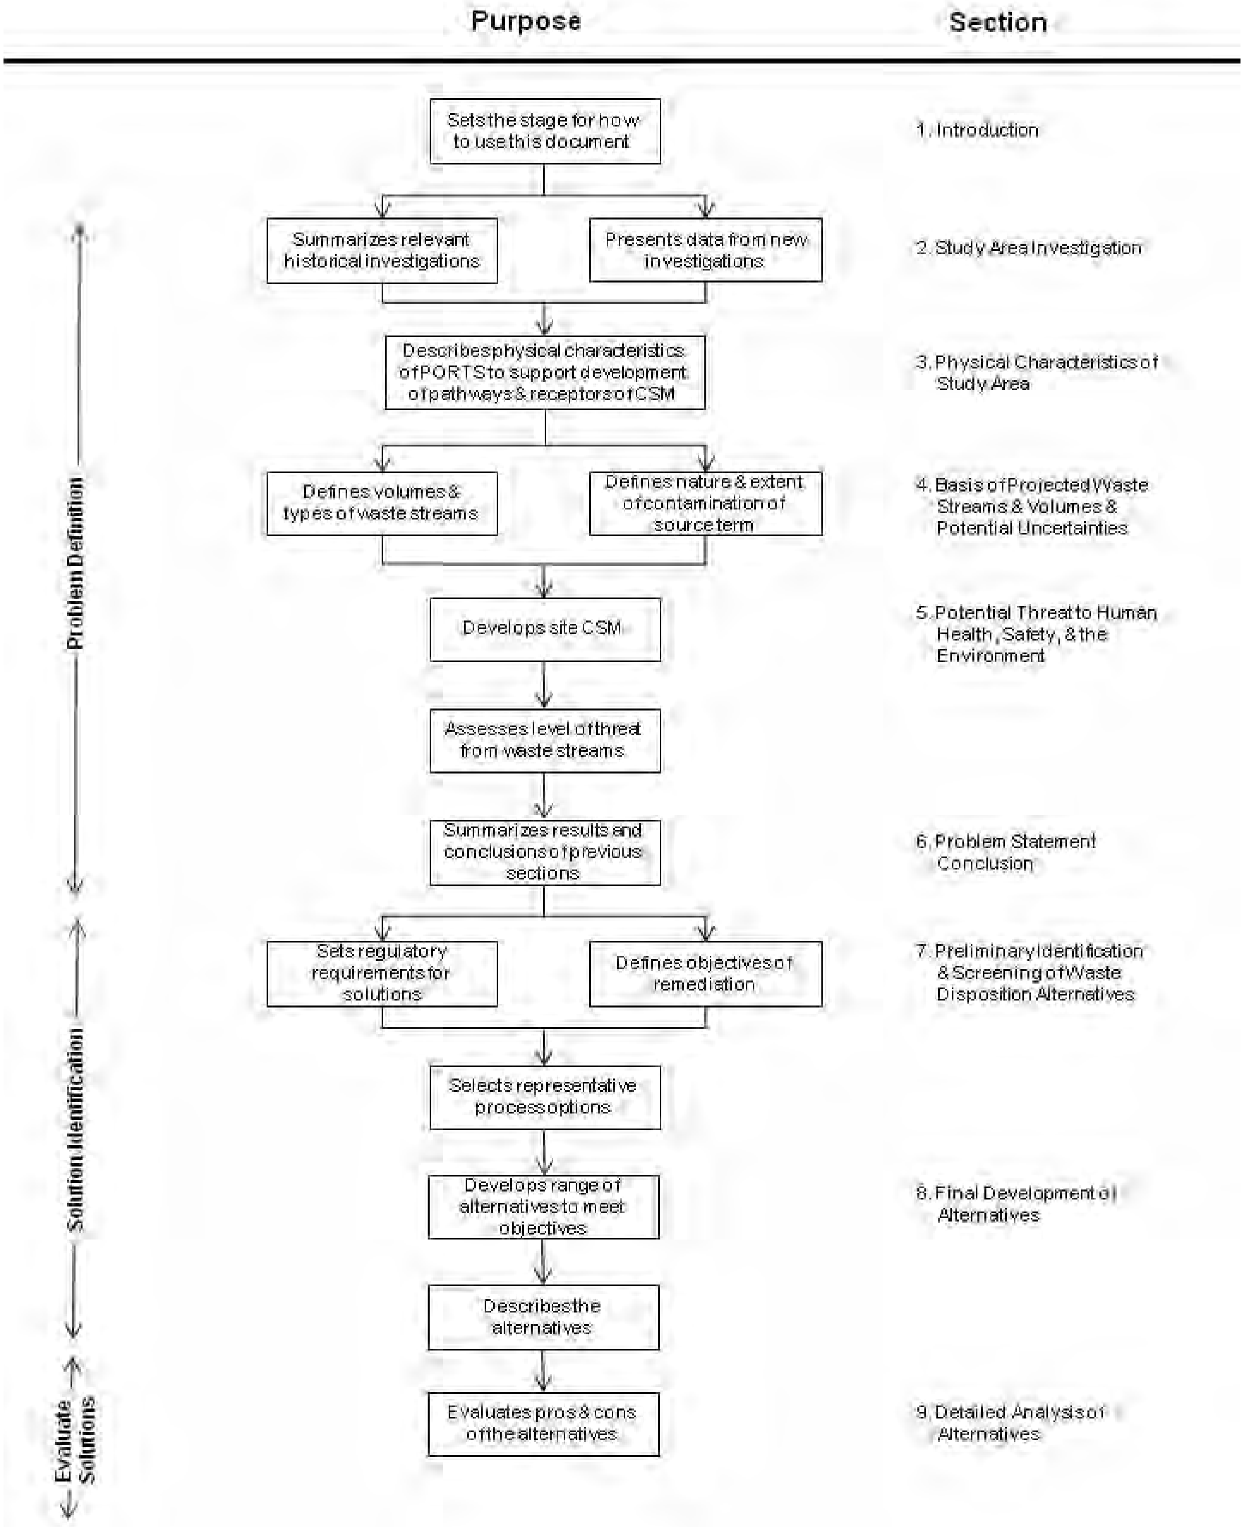

Figure 1.3. Flow Diagram of the PORTS Waste Disposition RI/FS Report by Section

development and cost-estimating purposes, and to define the nature and extent of contamination for developing source-term estimates. In support of Section 4, Appendix A presents recently collected data on contamination levels in the process equipment. Appendix E contains detailed waste volume estimates.

Section 5 – Potential Threat to Human Health, Safety, and the Environment
Section 5 is intended to summarize the potential risks associated with the PORTS buildings and process equipment under a no-action alternative. A streamlined, qualitative risk evaluation is presented.

For a no-action decision, the streamlined evaluation concludes that the contaminant concentration levels present in the D&D waste streams can result in hypothetical long-term human health threats of sufficient magnitude to justify the need for a remedial action. This conclusion and the results from the risk assessment serve as one of the cornerstones for setting the remedial action objectives (RAOs) presented in Section 7.

Section 6 – Summary of Problem Statement
Section 6 summarizes the primary investigation results and conclusions from Sections 2 through 5 of the RI/FS report. It is intended to serve as a foundation for the FS process presented in Sections 7 through 9. Readers who want to pass over the details in Sections 2 through 5 and their supporting appendices can use Section 6 to prepare for the FS portion of the report.

Section 7 – Preliminary Identification and Screening of Waste Disposition Alternatives
Section 7 presents the chemical- and location-specific ARARs, RAOs, and general response actions (GRAs) for the development of waste disposition alternatives. This section identifies and screens potential technology types so representative process options can be identified for developing alternatives. During the identification process, each relevant technology and process option is evaluated in terms of implementability, effectiveness, and cost. One on-Site engineered disposal process option and three off-Site disposal options are selected in this section for development into alternatives.

Three appendices support the identification of alternatives in Section 7. Appendix F presents the ARARs and pertinent TBC guidance related to waste disposition. Appendix G is an engineering study of process options to mitigate void-related subsidence in the disposal of process building equipment and piping. Appendix H is a detailed evaluation of potential sources of fill for operating a potential OSDC.

Section 8 – Final Development of Alternatives
Section 8 explains the assembly of representative process options into final remedial action alternatives, each aimed at achieving the RAOs and complying with ARARs. This section provides a sufficiently detailed description of each alternative to support the evaluation of alternatives in Section 9.

Appendix I supports Section 8 by presenting the development of draft modeled WAC for on-Site disposal, as required by the DFF&O. Appendix J presents a conceptual design for a potential OSDC at a representative location to support the development of an on-Site alternative. Justification for the representative location can be found in Appendix D.

Section 9 – Detailed Analysis of Alternatives
Section 9 presents an individual analysis of each final alternative developed in Section 8, along with a comparative analysis of the alternatives using the nine CERCLA criteria recognized in the DFF&O. Descriptions of the individual analyses are presented, including a NEPA evaluation of potential impacts. The intent of this section is to distinguish the advantages, disadvantages, and tradeoffs between the alternatives.

Appendix K provides a compilation of supporting technical evaluations conducted to assist in the detailed analysis of the alternatives, including an on-PORTS and off-PORTS transportation risk analysis, an evaluation of greenhouse gas impacts resulting from transportation of waste from PORTS, and an examination of passive leachate treatment system failure for a hypothetical OSDC. Appendix L presents the development of the cost estimates and associated cost estimate backup for each of the remedial action alternatives.

Section 9 illustrates that the major differentiating elements between on-Site and off-Site disposal are issues surrounding long-haul transportation and cost. Both options are protective and meet all applicable regulations or provide a basis for a waiver. Included in this section is an evaluation of the impacts and implications on an on-Site disposal alternative of co-disposal of wastes generated under the Ohio Consent Decree (RC-2, EC-1) with the D&D waste (RC-1).

Section 10-Ancillary Benefits of Alternative 2

Section 10 is the final section and it describes ancillary benefits that may be achieved through the use of an on-Site disposal option. This section is provided for the decision makers to understand the overall benefits of on-Site disposal from a programmatic standpoint that are not part of the DFF&O decision.

DFF&O Compliance Matrices to Assist in Review of the RI/FS

The DFF&O contains requirements and attached outlines for developing RI and FS reports. It also contains a generic statement of work (SOW) for conducting and documenting RIs and FSs. To assist readers with mapping the contents of this RI/FS report to the RI and FS report outlines and SOW requirements, a set of compliance matrices is included. These can be found after Section 11 (the references) in the main report.

Each of the three compliance matrices serves as a crosswalk of requirements and how those requirements were addressed in the individual sections and appendices of the RI/FS report. The first compliance matrix focuses on RI report requirements (Attachment A, Appendix E, Outline E-1 of the DFF&O). The second matrix focuses on FS report requirements (Attachment A, Appendix G, Outline G-1 of the DFF&O), and the third matrix focuses on the RI and FS SOW itself (Attachment A of the DFF&O).

Readers can detach the provided matrices and use them to track compliance with all major DFF&O requirements and reporting obligations.

2. STUDY AREA INVESTIGATION

Problem definition begins by assimilating the historical and current data that have been collected. These data are then used in subsequent stages of problem definition to build a CSM that defines the source of contamination, the fate and migration potential of the contamination, and the exposure to potential receptors. The intent of Section 2 is to present the relevant historical and current data that are used in later sections. Section 2 provides an overview of previous environmental restoration investigations and waste disposition planning activities (Section 2.1), and it introduces the recent investigations conducted to support development of a CSM and to develop alternatives (Section 2.2). The primary objectives of these recent investigations were to: (1) collect physical samples from select process gas equipment (PGE) to characterize waste constituents that may be present in the D&D waste to support all alternatives and (2) collect hydrogeological, geochemical, and geotechnical data identified during data quality objective workshops to support development of WAC and selection of a location for a potential OSDC. To identify the media to be sampled during the sampling efforts and specify the methods for collecting and analyzing the samples, two separate SAPs were prepared. A summary of the sampling conducted and a summary of the results from the various sampling programs are presented in this section.

This section is then completed with an explanation of deviations from the initial SAPs (Section 2.3) and an assessment of how the data meet the quality assurance (QA)/quality control (QC) requirements identified in the SAPs (Section 2.4).

2.1 PREVIOUS INVESTIGATIONS

Numerous environmental investigations have been conducted in and around PORTS by DOE. These investigations were focused primarily on releases and impacts to the environment that occurred exterior to the process buildings. While remediation of the environmental contamination is not a focus of this RI/FS, previous studies discussed in the following sections provide useful information about past operations originating in the process buildings at PORTS and provide details on the environmental setting, which are used to develop a CSM for the current waste disposition RI/FS. Results from these studies can be used to assess future contamination migration potential if no action is taken and to identify chemicals of potential concern (COPCs).

2.1.1 Environmental Restoration

The DOE Environmental Restoration Program was established in 1989 to identify, control, and remediate environmental contamination at PORTS. Because PORTS is a large plant, it was divided into quadrants to facilitate the environmental contamination investigation and cleanup process. The Environmental Restoration Program was established to fulfill the cleanup requirements of the Ohio Consent Decree and Administrative Consent Order signed in June 1997.

DOE has completed the description of current environmental conditions, RFIs, and a cleanup alternatives study/corrective measures study for each quadrant, as summarized below. The four quadrant RFIs, implemented between February 1991 and July 1994, collected approximately 1,250 soil samples and 500 groundwater samples from 77 SWMUs. These investigations and reports have detailed the characteristics of PORTS that are pertinent to the waste disposition evaluation, characterized the nature and extent of contamination at PORTS, and provided a robust dataset that covers the primary industrial area of PORTS. The primary sources of information include the RFIs for the four quadrants (DOE 1996a, 1996b, 1996c, 1996d) and the corresponding corrective measures studies (DOE 1998a, 1998b, 2000b, 2001a).

The RFIs, in addition to defining and characterizing sources of contamination and delineating the nature and extent of contamination at many waste management units, concluded that groundwater contamination had the potential to migrate off PORTS, but the plume movement was slow. With the exception of Quadrant I, where the Gallia is continuous to off-PORTS areas, the RFIs concluded that other areas of groundwater contamination would likely discharge to surface water prior to migrating off PORTS. The RFIs also concluded that primary contributors to risk included several metals (arsenic, beryllium, chromium, cadmium, nickel, and vanadium), technetium-99, uranium isotopes, PCBs, polycyclic aromatic hydrocarbons (PAHs), and chlorinated solvents (e.g., TCE).

The *Quadrant I Cleanup Alternatives Study/Corrective Measures Study Final Report for Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2000b) was approved by Ohio EPA in 2000. In 2001, Ohio EPA issued the decision document for Quadrant I, which provided the required remedial actions for the X-749/X-120 groundwater plume, Quadrant I Groundwater Investigative Area (the 5-Unit Groundwater Investigative Area), and X-231A/X-231B Oil Biodegradation Plots, to address TCE contamination. Remedial actions required for the X-749B Peter Kiewit Landfill were provided in separate decision documents issued by Ohio EPA in 1996 and EPA in 1997 to address organic compounds and radionuclides emanating from the landfill. In 2004, TCE was detected in groundwater from an off-PORTS monitoring well south of the DOE property. TCE levels were less than the drinking water standard of 5 µg/L. Subsequent actions were implemented, including the addition of extraction wells in the X-749 South Barrier Wall area, to mitigate further migration of the groundwater plume. Monitoring data indicate these wells are functioning as intended to reduce contaminant migration (DOE 2012b), and current data indicate that the off-PORTS TCE contamination has been reduced to non-detect levels.

The *Quadrant II Cleanup Alternatives Study/Corrective Measures Study Final Report for Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2001a) was approved by Ohio EPA on March 26, 2001. After approval of the document, however, Ohio EPA requested an amendment to the approved study to address additional remedial alternatives for the X-701B area. Amendments were submitted in 2001 and 2002. In January 2003, Ohio EPA informed DOE that a separate Preferred Plan and decision document would be prepared for the X-701B area. Ohio EPA issued the X-701B Preferred Plan in September 2003 and the X-701B Decision Document in December 2003 to address TCE in groundwater.

Phase I field activities for the X-701B groundwater remediation began in September 2005 to determine operating parameters for the oxidant injection system, including the injection methodology, rate, pressure, and spacing; reagent concentration; and reagent volume. Based on the results of the Phase I field activities, DOE developed a work plan for completion of the groundwater remediation at X-701B. This work plan was approved by Ohio EPA in September 2006. The first phase of oxidant injections was completed during October 2006, with Phase II injections completed in April 2007 and August 2007. In 2008, additional Phase II injections were completed in April, June/July, and October. Following the October oxidant injections, DOE-PORTS requested an independent review of the X-701B project by DOE Headquarters to evaluate remediation results to date and provide recommendations for a path forward. The review determined the injections had been moderately successful in the upper and middle soil horizons, but they had not been effective in addressing the TCE contamination in the lower Gallia sand and the upper Sunbury shale. As a result of the review, DOE completed an Interim Remedial Measure in 2009 and 2010 that achieved a significant reduction in TCE in the deeper horizons. The Interim Remedial Measure included excavating the soil horizons, blending them with oxidants, and then replacing them back into the excavation in a manner that reconstructed the original geologic stratigraphy.

The *Quadrant III Cleanup Alternatives Study/Corrective Measures Study Final Report for Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 1998a) was approved by Ohio EPA in 1998. The decision document for Quadrant III required phytoremediation of the TCE groundwater plume near the X-740 Waste Oil Handling Facility. A *Supplemental Evaluation to the 2003 Five-Year Evaluation Report for the X-740 Phytoremediation System at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2007a), submitted to Ohio EPA in January 2007, found that the phytoremediation system had not performed as expected in removing TCE from groundwater in this area. In response to this evaluation and Ohio EPA comments, DOE submitted a work plan for additional remedial activities in the X-740 area. Three rounds of oxidant injections were completed in the summer of 2008 to remove TCE from the groundwater. The oxidant briefly reduced TCE concentrations but concentrations returned to typical levels by the end of 2008 (DOE 2011b). In 2010, enhanced anaerobic bioremediation was approved and implemented as a pilot study to address the plume at the X-740 area.

The *Quadrant IV Cleanup Alternatives Study/Corrective Measures Study Final Report for Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 1998b) was approved by Ohio EPA in 1998. DOE received the decision document for Quadrant IV in 2000. No new remedial actions were required in Quadrant IV. (Remedial actions had already taken place at the X-344D Hydrogen Fluoride Neutralization Pit, X-735 Landfills, X-611A Former Lime Sludge Lagoons, and X-734 Landfills.) The *First Five-Year Review for the X-734 Landfill Area at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* was submitted to Ohio EPA in 2008 (DOE 2008). This report found that construction of the caps on the landfills had achieved RAOs by isolating contaminants in soil and sediment from potential receptors. The caps are preventing contaminants in soil and sediment from migrating to groundwater and surface water. Ohio EPA approved the report in December 2008.

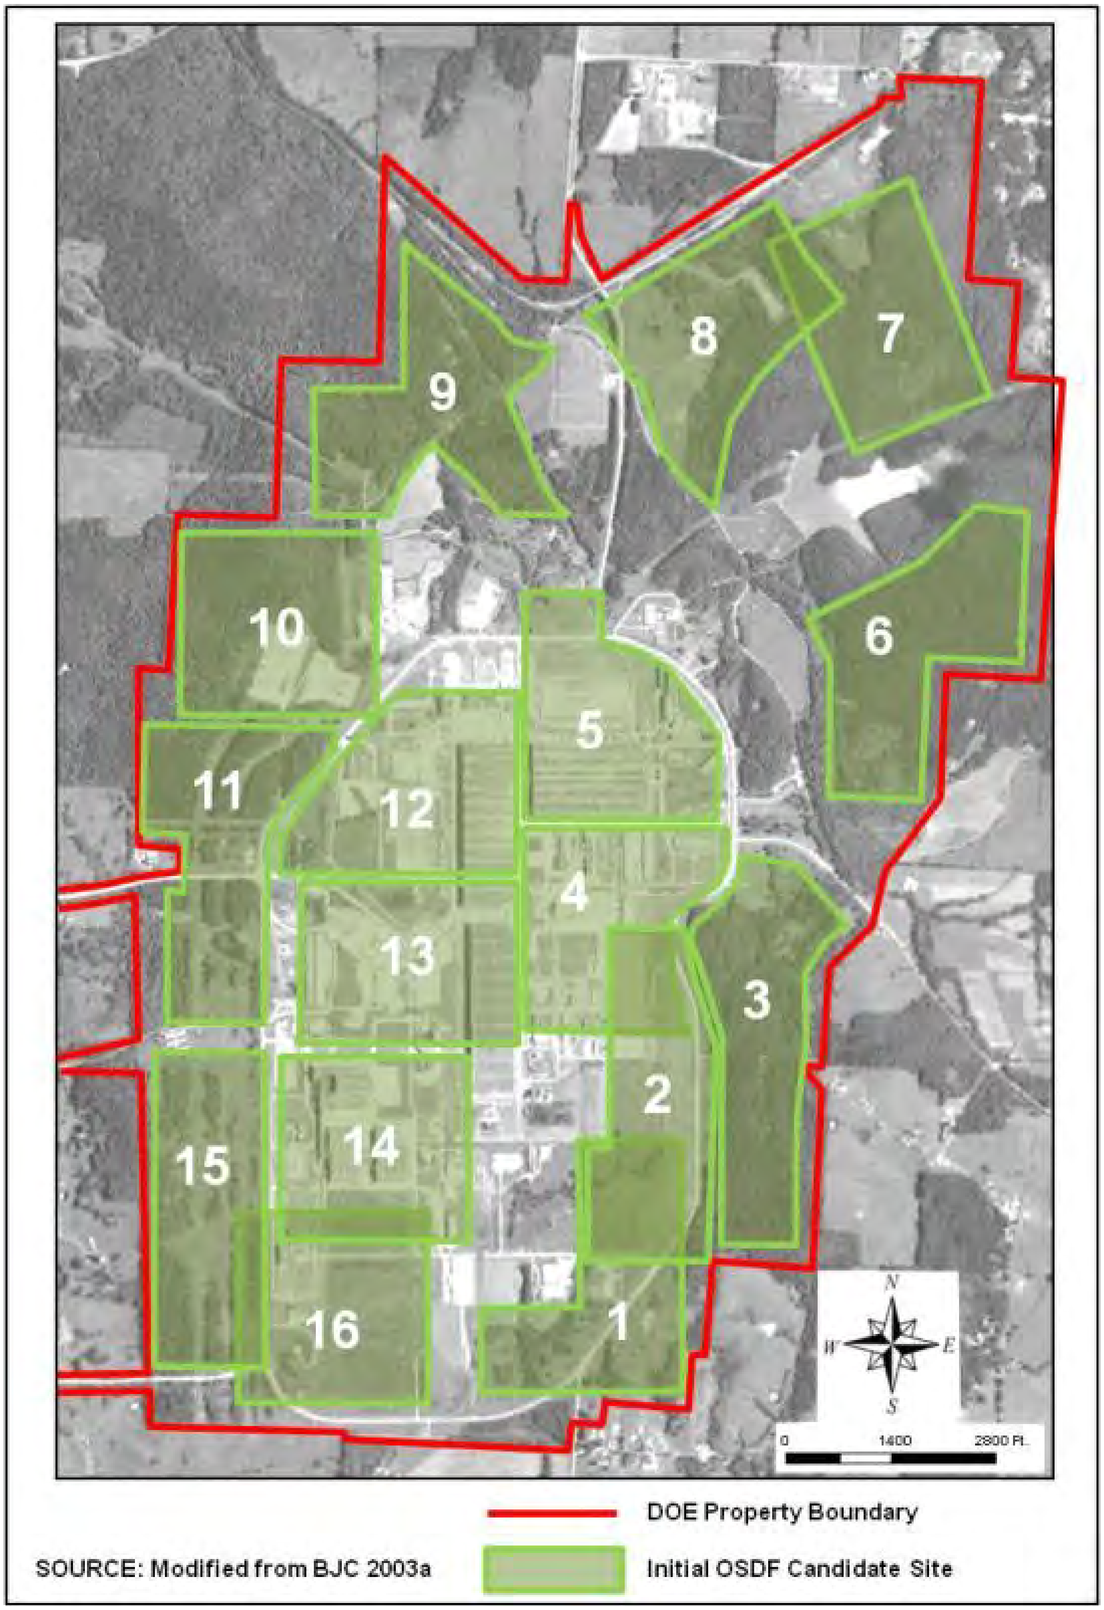
2.1.2 Waste Disposition Planning

From 2002 through 2009, DOE prepared several documents about a potential waste disposal facility at PORTS, during which time off-PORTS shipments of waste continued. These reports covered subjects that included the following:

- Preliminary assessment (November 2002) (Bechtel Jacobs Company LLC [BJC] 2002)
- Identification and screening of candidate locations (April 2003) (BJC 2003a)
- Waste volume/characteristics inventory (April 2003) (BJC 2003b)
- Conceptual design of a potential waste disposal facility at PORTS (August 2006) (DOE 2006).

The identification and screening report (BJC 2003a) considered a potential waste disposal facility at PORTS that would consist of an above-grade, RCRA-compliant earthen disposal cell with a capacity of 4 million cy and a waste footprint of 42 acres. The report estimated an additional 108 acres would be needed for ancillary facilities to support initial operations and facilities needed for staging, temporary storage, transport support equipment decontamination, storm water management, security, weighing, and administration. The total footprint for the entire disposal facility would be approximately 150 acres.

PORTS-specific screening criteria were developed to identify and evaluate a wide range of candidate locations for the facility. The screening criteria were based on ARARs for siting a mixed hazardous and radioactive waste disposal facility, as well as other site-specific criteria (geologic, hydrologic, and seismic conditions; land use plans; topographic features; etc.). Sixteen candidate locations were initially selected throughout the DOE property at PORTS (Figure 2.1). During this preliminary siting effort, DOE requested at least one of the candidate locations be in an area that has been impacted by former waste management activities and at least one candidate location be in an area that has not been impacted.



SOURCE: Modified from BJC 2003a

Figure 2.1. Initial Candidate Locations for a Potential Waste Disposal Facility at PORTS

The initial candidate locations met preliminary siting requirements and could reasonably be considered acceptable areas for placement of a potential disposal facility at PORTS. To be considered as an initial candidate location, the location had to be entirely within DOE-owned property, contain at least 150 contiguous acres, and not be technically or administratively impracticable or cost prohibitive. The potential locations went through two screening stages against the siting criteria, which resulted in three sites being recommended for further evaluation in an RI/FS.

The *Portsmouth Gaseous Diffusion Plant Decontamination and Decommissioning Project On-site Waste Disposal Facility Conceptual Design - Final Submittal* (DOE 2006) provided a conceptual design and life cycle cost estimate for construction of a potential disposal facility at PORTS. The document provided conceptual-level descriptions of disposal cell design, operational requirements, and capping/post-operations requirements.

The potential disposal facility was proposed at PORTS for disposal of waste from D&D of the Portsmouth GDP. The design report included the following general benefits of such a facility:

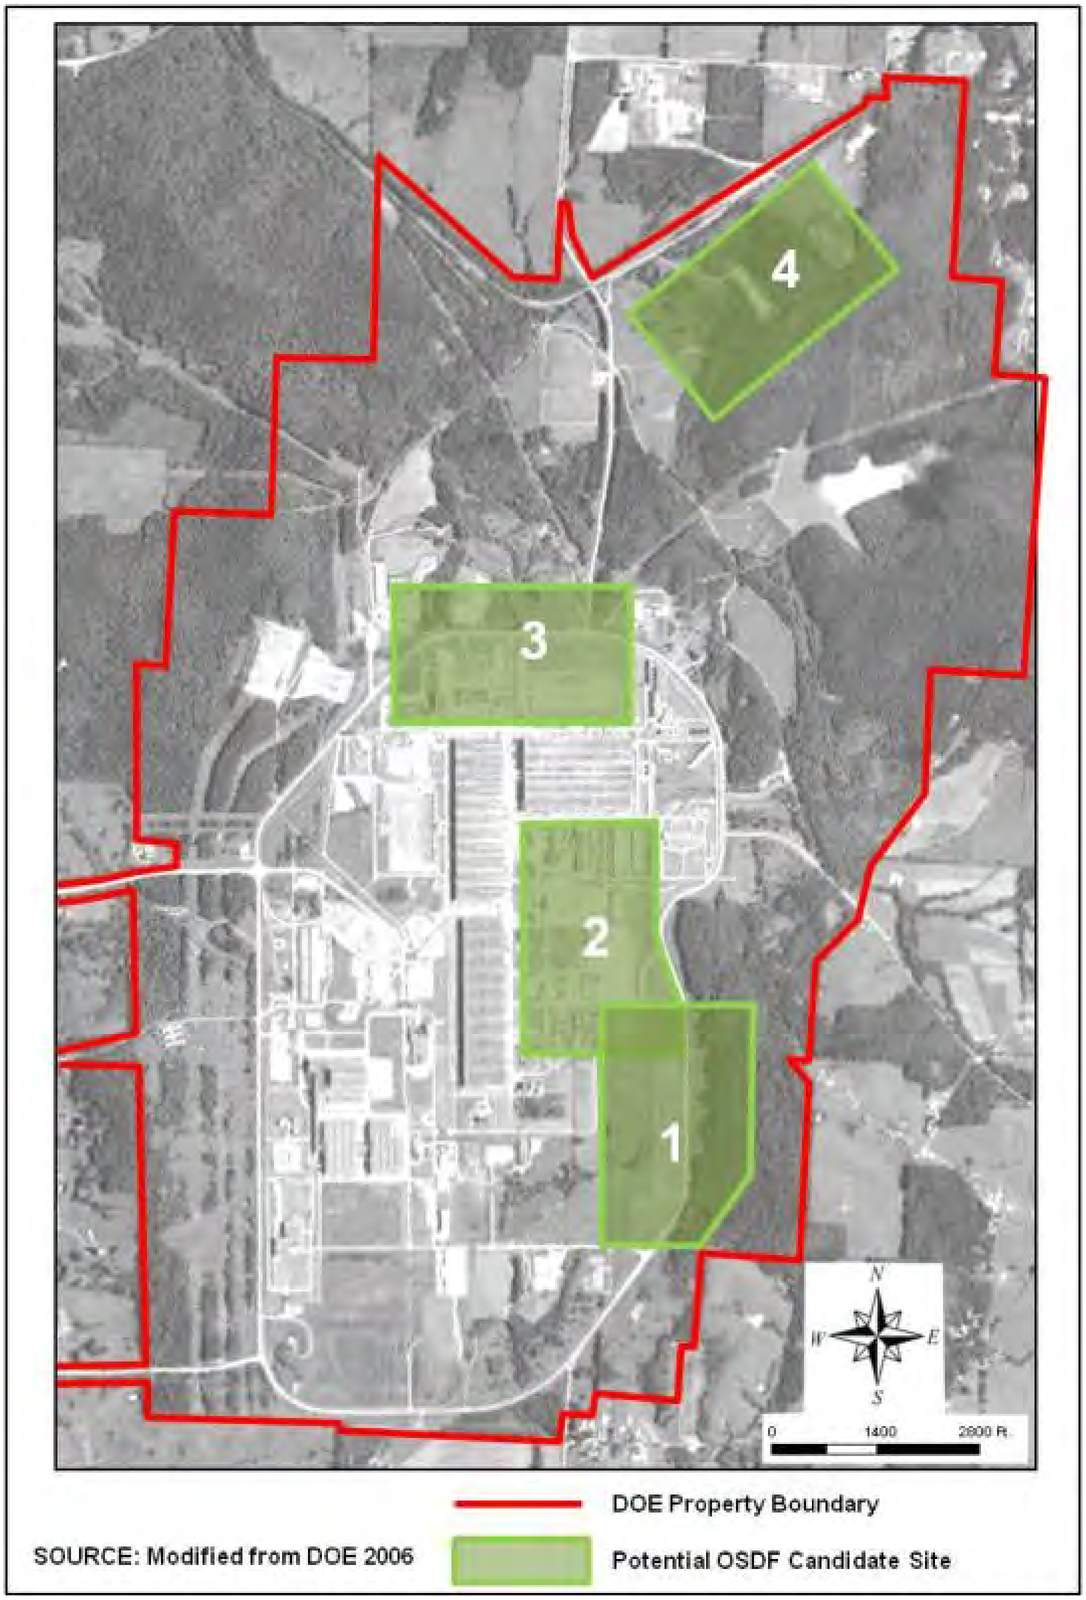
- Acceleration and cost reduction of the D&D activities
- Reduced risks and potential injuries from transport of wastes to an off-PORTS facility
- Greater level of certainty that long-term disposal capacity would be available at PORTS to support D&D and remediation activities
- Provision of jobs and opportunities within the local economy.

The conceptual design was based on the waste types and volumes estimated in the waste management plan (Theta Pro2Serve Management Company, LLC [TPMC] 2006a) (Section 9.7 of the 2006 Conceptual Design Report). Wastes excluded from the potential disposal facility at PORTS included liquid waste, transuranic (TRU) waste, RCRA land-banned waste, USEC-generated waste, municipal sanitary waste, and waste generated off PORTS. With an assumed area of 150 acres needed for a potential disposal facility at PORTS, the 2006 Conceptual Design Report recommended four locations that the project team considered to be candidate locations requiring further assessment (Figure 2.2).

2.1.3 Existing Study Area Data

Development and evaluation of an on-Site disposal alternative pursuant to the DFF&O requires data on the geochemical properties of the soil for groundwater modeling and WAC development, as well as hydrogeological characteristics of the potential location for a disposal facility. Geotechnical data are required to determine soil properties such as subsidence, compaction, permeability, etc. for facility design. Hydrogeological data are required to evaluate compliance of the location of such a facility with ARARs such as the State of Ohio waste disposal siting requirements.

Considerable existing geologic and hydrogeologic data are available for PORTS, including data from more than 1,600 soil borings. This data can be found in facility investigation and corrective measures reports for the four quadrants, as well as in annual groundwater reports. Data regarding depth to groundwater are sufficient over most of the Facility. However, as previously stated, minimal existing data are available for some potential disposal facility locations. Therefore, additional investigation activities have occurred at potential locations to supplement existing information.



SOURCE: Modified from DOE 2006

Figure 2.2. Four Potential Locations for a Disposal Facility Considered in a 2006 Conceptual Design Report at PORTS

Existing geochemical data include total organic carbon (TOC) and cation exchange capacity data collected during previous investigations and PORTS-specific soil adsorption coefficients (K_d values) derived for a vadose zone soil-leaching study performed in 1994. The TOC dataset, which has a lognormal distribution, ranges from 0.00008 to 0.0082 kg/kg with a geometric mean of 0.0009 kg/kg or 0.09 percent. The cation exchange capacity dataset has a normal distribution ranging from 4.8 milliequivalents (meq) per 100 g to 25.0 meq/100 g with a mean of 13.9 meq/100 g (DOE 2012a).

The K_d values for contaminants of interest are both chemical- and site-specific. The K_d value of an organic contaminant, such as TCE, is calculated using the TOC values from the soil. The K_d values are used for fate and transport modeling and have an indirect influence on the transport of contaminants. That is, the greater the K_d value, the more adsorption to soil, which results in reduced contaminant transport through the groundwater pathway. The K_d values for selected metals at PORTS were measured experimentally to support preliminary remediation goal (PRG) development in 1994 (DOE 1995a).

Site-specific K_d values were measured for antimony, arsenic (V), barium, cadmium, chromium (III and VI), lead, manganese, and mercury using a 24-hour, batch-type procedure (American Society for Testing and Materials [ASTM] D4646-87) on Minford silty, clayey soil. The values determined from the previous study are shown in Table 2.1.

Table 2.1. Soil Adsorption Coefficients Previously Measured at PORTS

Contaminant	Soil Adsorption Coefficient (mL/g)
Antimony	422
Arsenic (V)	208
Barium	545
Cadmium	48.5
Chromium (III)	810
Chromium (VI)	7
Lead	28,300
Manganese	16.5
Mercury	41

Source: DOE 1995a

DOE = U.S. Department of Energy

Geotechnical information is sparse for the locations being evaluated for a potential OSDC. Most existing geotechnical data are related to foundation studies for the GDP facilities and centrifuge project facilities. Therefore, geotechnical information specific to each of the current four study areas was collected to support the current RI/FS.

The Minford consists primarily of over-consolidated lean clays and silts. Based on several thousand split-spoon samples, fat clays constitute approximately 8 percent of the Minford, lean clays constitute about 59 percent, and silts constitute approximately 33 percent. Plastic limits of the clays are relatively constant with depth and average approximately 20 percent. Liquid limits typically decrease with depth. In situ moisture contents are generally within 5 percent of the plastic limit, which is typical for over-consolidated clays. As expected with over-consolidated soils, the Minford soils are quite strong (Law Engineering 1978), as evidenced by standard penetration resistance values.

Historical analytical data for contaminants present in soils within the potential OSDC study areas being evaluated in this RI/FS have been reviewed and compared to Minford soil background concentrations for PORTS and applicable risk-based PRG values for the purpose of determining if residual contamination from plant operations is present in these locations. Even where data may exceed the background value, it may still fall within the background range. In the 1996 background study, the established background values, or the upper tolerance limit for the background dataset, represent the maximum concentration of naturally occurring constituents that would be expected in the environment. More specifically, the established background values contain 95 percent of all possible sample measurements in the background dataset (DOE 1996e). Risk-based PRG values were used for screening to aid in identifying if an area warranted further evaluation. The RI/FS Work Plan (DOE 2012a) provided a summary of the contaminant data at each current study area, and an additional discussion of data collected for this RI/FS is presented in the following sections of this RI/FS report.

2.1.4 Historical PORTS D&D Data

Several plant support buildings and structures have been demolished under previous removal actions. The buildings with waste characterization data available are: X-100, X-100B, X-101, X-102, X-103, X-106, X-109C, X-334, X-342C, X-344, X-600, X-600B, X-600C, X-605, X-624-1, X-633, X-744S, X-760, and X-770. These buildings and structures ranged in complexity from simple warehouses and sheds having no contamination to complex facilities that were heavily contaminated with radionuclides, chemicals, and PCBs. Samples were collected from these buildings and structures to support waste characterization prior to disposition. Some individual buildings and structures had the potential for radiological, volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), heavy metals, corrosives, and biological hazards contaminants to be present. Knowledge of materials or chemicals used in the buildings was the basis for identifying additional COPCs and developing the characterization plans. Based on the proximity of the buildings to areas of contamination or to historic releases, it was assumed that PORTS-related contamination potentially existed at every building. As these buildings span the range of complexity, they are representative of the majority of the waste streams that are anticipated to be generated from the D&D of PORTS.

The results from the waste characterization sampling effort are summarized in Table 2.2. As noted in the table footnotes, various buildings were sampled and analyzed for metals, commonly used organics, radionuclides, and samples were also analyzed using the Toxicity Characteristic Leaching Procedure (TCLP). These results represent the minimum and maximum values for selected constituents. The building or structure in which the minimum or maximum occurred is also identified. Only detected values are presented. Note that not all sample results have been validated. For example, buildings and facilities sampled prior to the DFF&O were sampled for internal purposes and did not have the same validation as more recent sampling plans developed under the DFF&O.

Table 2.2. Characterization Results from Previous Buildings and Structures

Inorganics/Organics	Minimum (mg/kg)	Building	Maximum (mg/kg)	Building

Uranium-235	0.00546	X-600	16	X-344	

Table 2.2. Characterization Results from Previous Buildings and Structures (Continued)

Radionuclides	Minimum (pCi/g)	Building	Maximum (pCi/g)	Building
Uranium-235/236	0.0198	X-334	1.06	X-106
Uranium-236	0.00746	X-770	0.523	X-600
Uranium-238	0.0173	X-600	325	X-344
Plutonium-239/240	0.0141	X-760	0.0283	X-760
Plutonium-242	0.0184	X-342C	0.0184	X-342C
Americium-241	0.029	X-760	0.029	X-760
Uranium-235 (weight %)	0.157	X-770	2.7	X-103

Bolded TCLP maximums represent exceedances of the TCLP limit.

Buildings with "mg/kg" results: X-100, X-100B, X-101, X-102, X-103, X-106, X-109C, X-334, X-342C, X-344, X-600, X-600B, X-600C, X-605, X-624-1, X-633, X-744S, X-760, X-770.

Buildings with TCLP (mg/L) results: X-100, X-100B, X-101, X-102, X-103, X-106, X-109C, X-334, X-342C, X-344, X-600, X-600B, X-600C, X-605, X-624-1, X-633, X-744S, X-770.

Buildings with "pCi/g" results: X-100, X-100B, X-101, X-102, X-103, X-106, X-109C, X-334, X-342C, X-344, X-600, X-600B, X-600C, X-624-1, X-633, X-744S, X-760, X-770.

PCB = polychlorinated biphenyl
TCLP = Toxicity Characteristic Leaching Procedure

Most of the maximum radionuclide values are low with slightly elevated uranium activities in X-344. The X-100 Administration Building is associated with maximum values of arsenic and chromium in TCLP extracts (with chromium exceeding the TCLP limit) and PCBs. PCBs in X-100 are mostly associated with ventilation duct gaskets and light ballasts. Several of the maximum values of other constituents (such as arsenic, lead, mercury, selenium, silver, thorium-230, and uranium-234) were also associated with the X-600 Steam Plant. Selenium in a TCLP extract from X-600 exceeded the TCLP limit.

2.2 SITE-WIDE WASTE DISPOSITION INVESTIGATIONS

There are information and data collection activities that occur at each primary stage of a remedial project. The three primary stages of a project are the decision-making stage where the RI/FS, Proposed Plan, and ROD are developed; the design stage; and the implementation stage where the remedy is installed or implemented. The implementation stage includes any necessary efforts to safely dispose of the waste. The data needs in a phased remedial project, as required by the DFF&O, can be organized in these three stages:

- Decision-making Stage: data necessary to support the development, comparison, and selection of remedial alternatives.
- Design Stage: data necessary to complete the final design of the selected remedial alternative according to the approved ARAR requirements and RAOs.
- Implementation/Waste Disposal Stage: data necessary to demonstrate ARAR compliance, determine WAC attainment, ensure worker safety, and document physical completion of the remediation.

There are three primary types of data or information available: (1) that available from process knowledge (such as from design drawings, past studies and reports, staff experience); (2) that from samples that are collected from environmental media or materials of construction and analyzed in a laboratory; and (3) that from field instrumentation (such as radiological surveys). The various stages of a project have a different degree of reliance on the types of information, as shown in Figure 2.3. Process knowledge, along with historical analytical data, is very useful during the decision-making stage of projects, but it often needs to be supplemented with additional data to answer questions specific to evaluating alternatives. For the waste disposition RI/FS, data quality objectives were developed and SAPs were written to fill siting information needs and WAC development information needs. Additionally, more information and data will be needed as the project progresses beyond the decision. There are pre-design efforts planned to better understand location conditions and to anticipate construction material behavior, including when the construction material is in contact with the waste that will be placed in a potential OSDC.

Collection of analytical data can be time consuming and expensive. Therefore, during each phase of the project, the need for additional analytical data is carefully considered. The DFF&O has specific requirements for data collection as well as specific plans identified to document the data collection activity. Figure 2.4 illustrates the various stages of the project and the information needs identified in the DFF&O.

Decision-Making Stage. During the decision-making stage of the project, the existing data and scope of the decision to be made are evaluated during development of the RI/FS Work Plan. During this process for the waste disposition RI/FS Work Plan, additional data for siting a potential OSDC and for calculating a modeled WAC were identified as being needed. The results from this data collection activity are presented in this section. A similar work plan was written for the process building RI/FS. The DFF&O requires consideration of additional data to evaluate alternatives and to identify waste streams and volumes. In that case, it was concluded that no new analytical data were needed to understand the scope of the D&D problem (presence of hundreds of potentially contaminated buildings) or to evaluate a demolition alternative. Instead, existing data and other process knowledge were sufficient to make a decision regarding whether to demolish the process buildings. But as discussed below, additional data are needed during design and implementation of the building D&D projects to demonstrate compliance with ARARs and WAC and to ensure safe working conditions.

Design Stage. During the design stage of a project, there is reliance on existing and additional analytical data. The DFF&O requires many types of work plans, including the RD/RA Work Plan, Pre-design Studies Plans, Regulatory Compliance Plans, Health and Safety Plans, and (if needed) Treatability Study Work Plans, all submitted for Ohio EPA review and approval/concurrence, as applicable. All of these plans would be generated during the design and implementation of a potential OSDC as well during the design and implementation of building D&D. As shown in Figure 2.4, the sampling documented in these plans supports various information needs required in the DFF&O. In addition, a WAC Attainment Plan would be developed to demonstrate how any waste generated would meet the WAC of the appropriate disposal facilities. Supporting these plans may be a number of additional SAPs, also submitted for Ohio EPA review and approval/concurrence as applicable.

	RI/FS/ROD	DESIGN	IMPLEMENTATION
DFF&O	- Support decision - Determine need for action - Support evaluation of alternatives - Define source areas - Location and description of buildings	- Refine understanding of threat	
Other	- Support +50%/-30% cost	- Define waste streams - Demonstrate WAC compliance - Support procurement	- Demonstrate protective - Demonstrate ARAR compliance - Demonstrate WAC compliance

Figure 2.3. Data Needs and Types

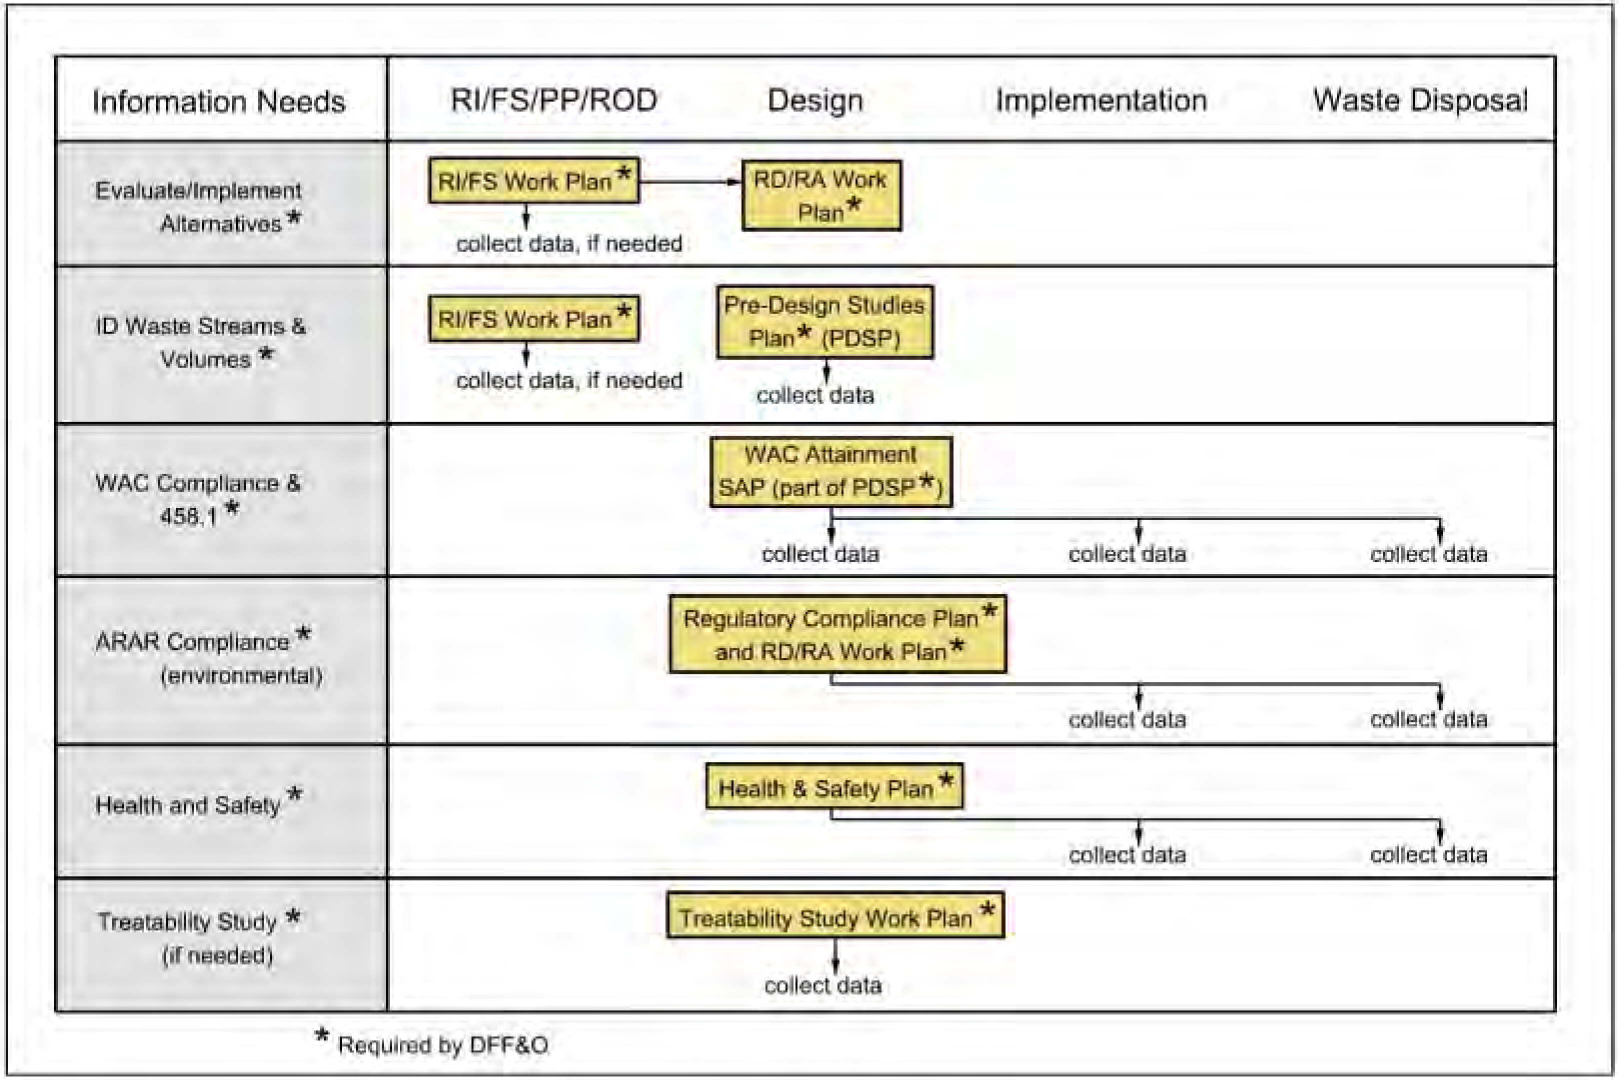

Figure 2.4. DFF&O Analytical Data Collection Requirements

Implementation of the sampling required by these SAPs and plans begins during the design and continues into the implementation stages of the project. An appropriate number of samples would be taken from each building or group of like buildings/structures or infrastructure for the D&D project. Each major D&D medium would be sampled in a manner consistent with the impact of its volume, the level of contamination expected, and the uncertainty of the contaminant level relative to applicable WAC and/or safety basis. The sampled media could include building steel, roofing, walls, floors, residual soils, slabs, subsurface utilities, ventilation ducting, heat exchangers, and nonprocess piping or equipment suspected of radiological or hazardous contamination. If needed, treatability studies may be needed to assess the effectiveness of a treatment technology on some waste streams to demonstrate compliance with land disposal restrictions (LDRs) or Corrective Action Management Unit (CAMU) treatment standards. The actual numbers and locations of samples required during the design stage of the process building D&D project would be determined on the basis of the applicable WAC for waste disposal, treatment requirements, and safety basis. Regulatory review and approval or concurrence, as applicable, of these SAPs would be required prior to implementation.

Implementation/Waste Disposition Stage. While implementing the D&D project, nondestructive assay (NDA) measurements would be performed on equipment or piping suspected of requiring uranium deposit removal and equipment being shipped for on- or off-Site disposal. In situ NDA might also be performed on the X-330 and X-333 converters to support material recovery, as necessary. Both sampled media results and NDA results would be used to segregate waste for recycling or off-Site disposal and would be used to demonstrate compliance with the WAC and ARARs, as appropriate.

The environmental sampling during D&D or during construction of a potential OSDC would be primarily of surface water and air to track any sediment and dust releases or potential releases of contamination and potential impacts on the environment, including on sensitive resources and on human health (on-PORTS workers and the public). Some of the data would be analytical from laboratories, and some would be from field monitoring efforts. This information would either allow a demonstration that environmental ARARs requirements are being met or would provide information to identify appropriate responses if a release of contamination occurs. Health and safety sampling may include radiological monitoring, industrial hygiene monitoring, or other sampling, including clearance samples from asbestos remediation areas, smear samples for radiological control, and metal coupon samples from equipment (as necessary) for cadmium and beryllium control programs.

Project-Specific Data Collection Strategy. Figures 2.5 and 2.6 illustrate the work plans/SAPs and sampling activities planned for each project. This Site-wide Waste Disposition Evaluation Project would determine and provide waste disposal/recycling options with associated WAC for all the wastes to be generated by the Process Buildings and Complex Facilities D&D Evaluation Project in a safe and ARARs-compliant manner.

In Figure 2.5, the general phased sampling strategy is presented for the Process Buildings and Complex Facilities D&D Evaluation Project. Most of the data needs such as WAC attainment and treatment requirements during the design and the implementation/waste disposition stages of the D&D would be determined by decisions made in the Site-wide Waste Disposition Evaluation Project. The plans and SAPs identified in Figure 2.5 would be developed for each of the three major process buildings. Data collection in the remaining process and support buildings may be conducted in groups with tailored plans and SAPs for each group. Data would be collected to support the design and implementation of safe and ARARs-compliant D&D and associated waste disposal of a major process building or a group of other smaller buildings. The data needed to demonstrate WAC compliance are the responsibility of the project generating the waste, and the approach for collecting this information is presented in Figure 2.5.

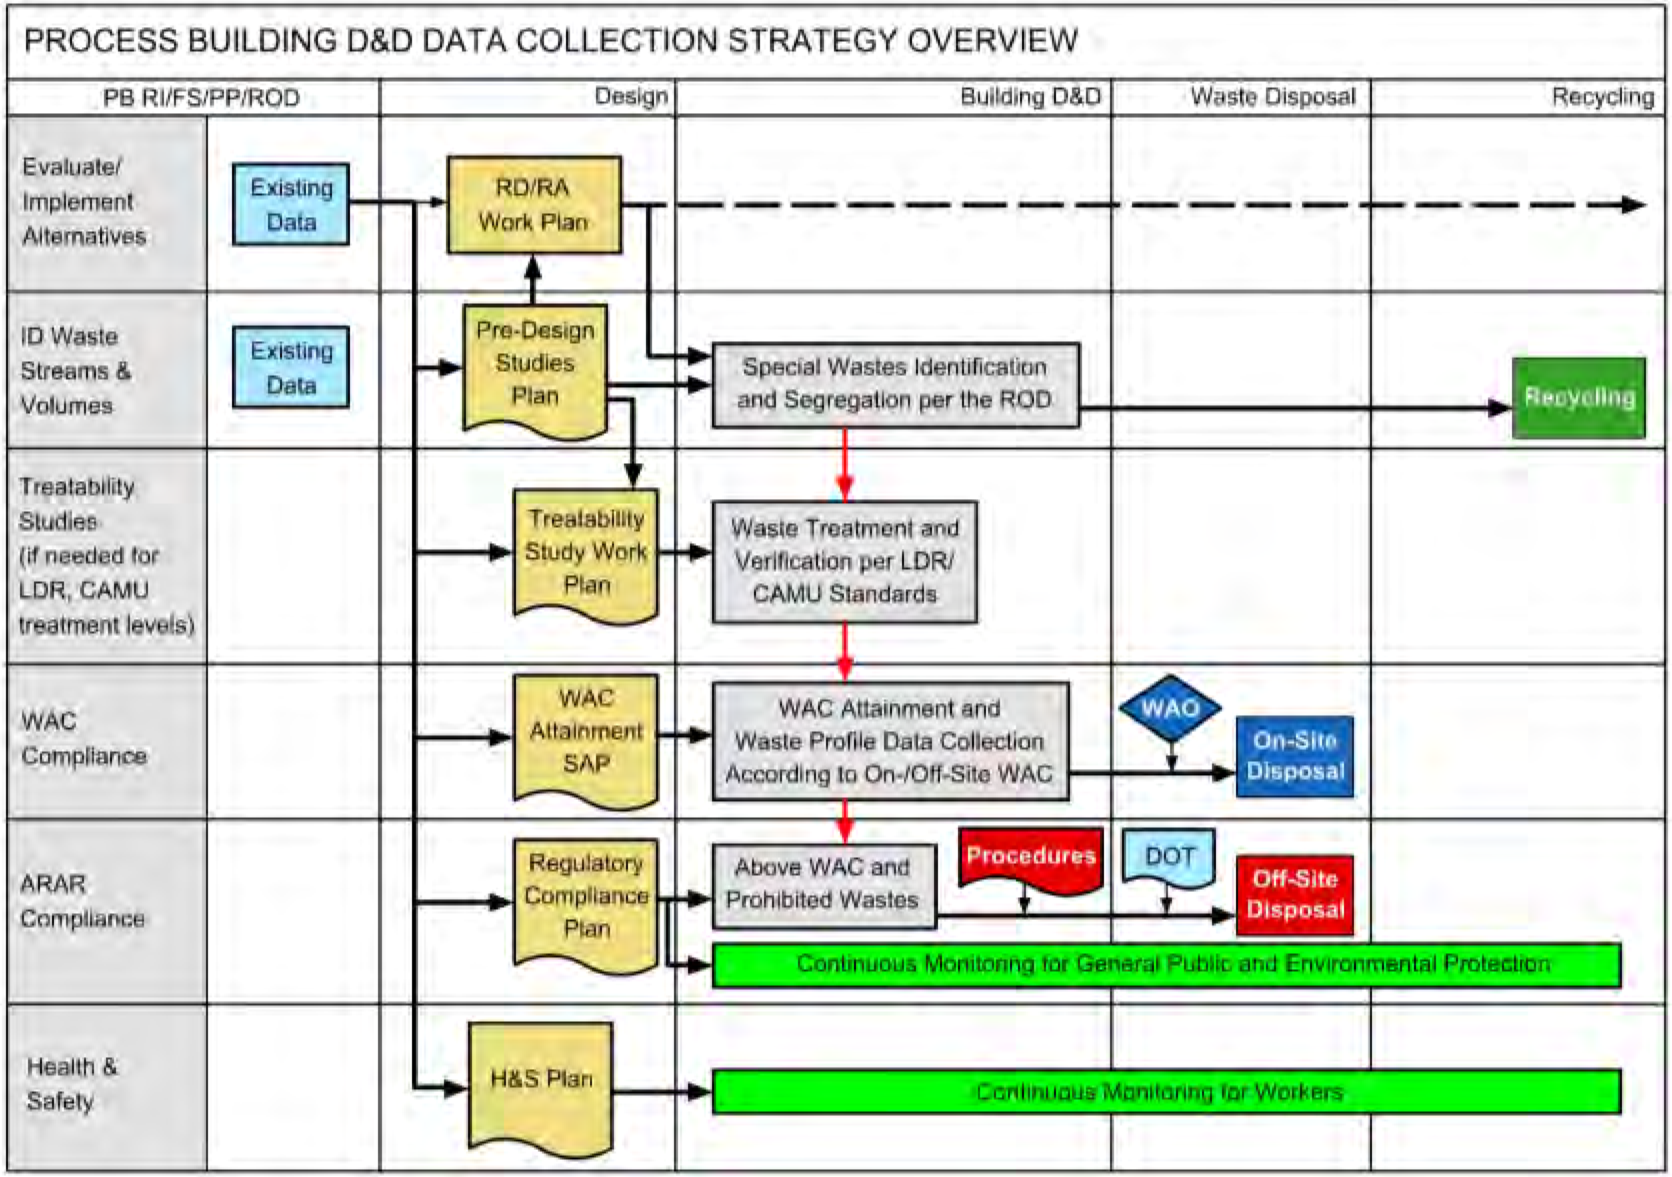

Figure 2.5. Process Building D&D Data Collection Strategy Overview

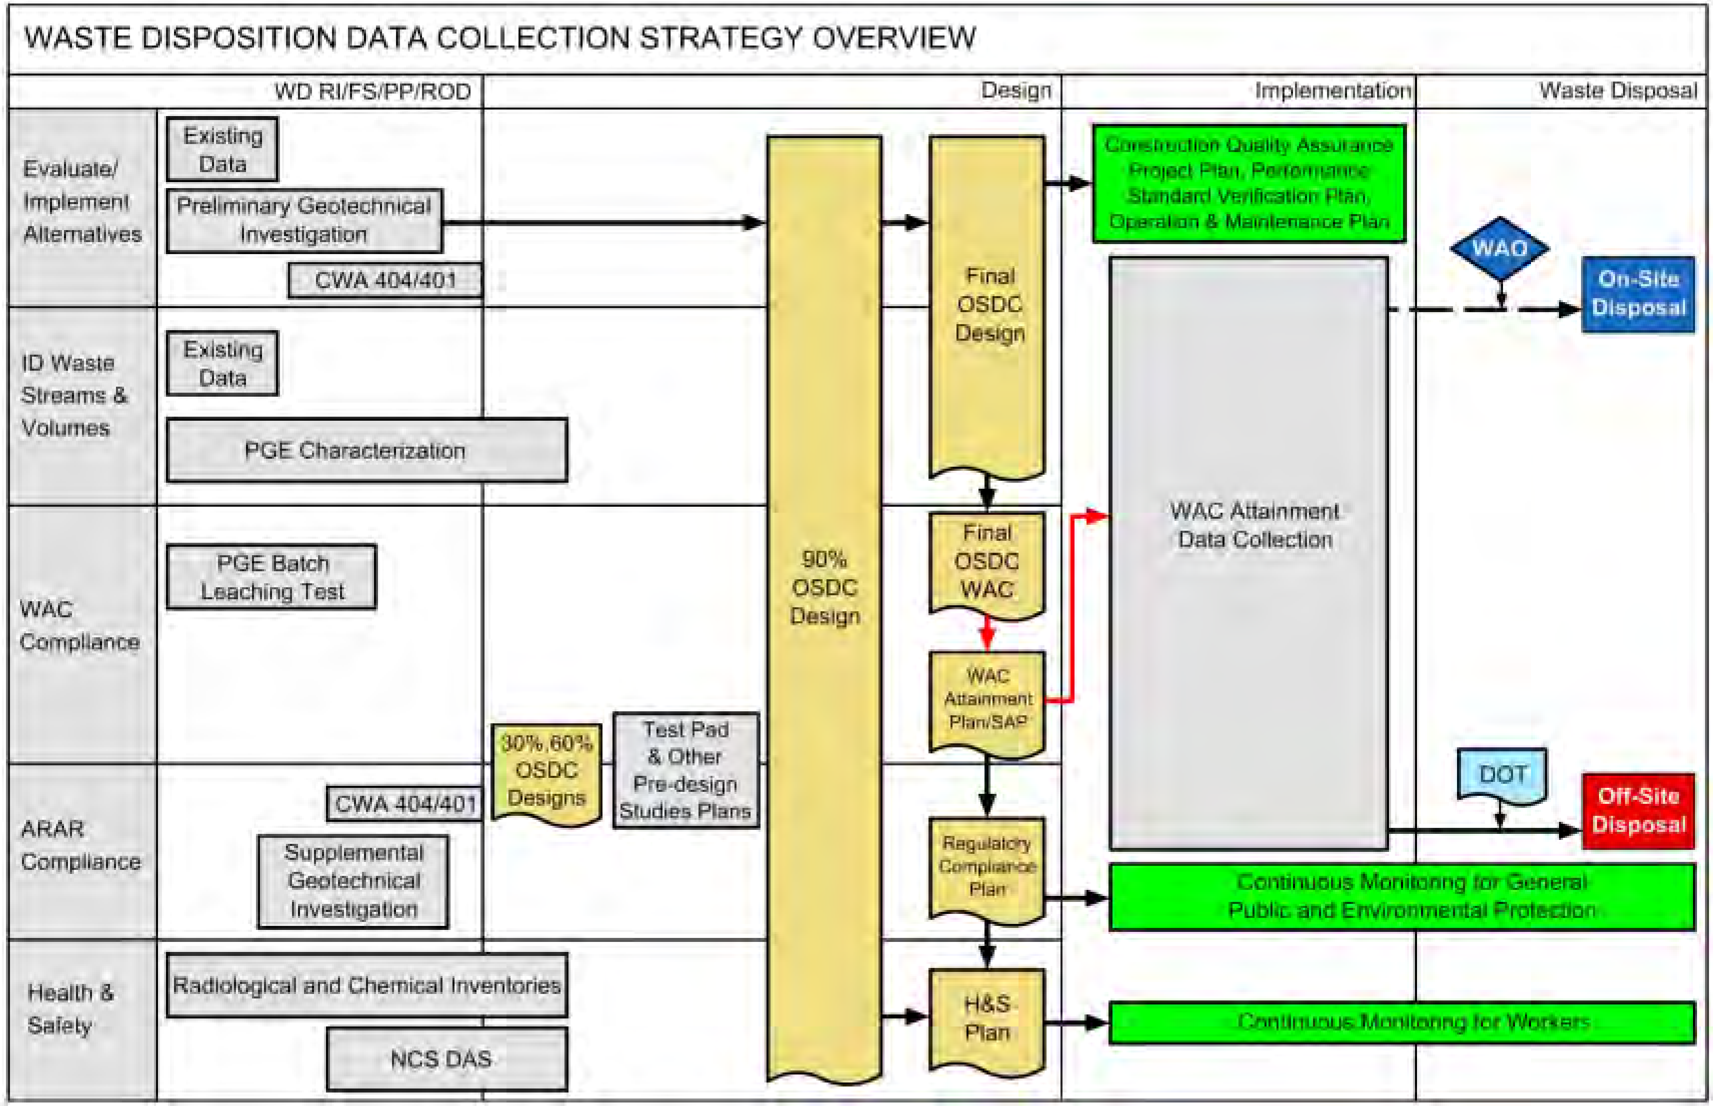

Note: Data collection will also occur during and after closure of a potential OSDC.

Figure 2.6. Waste Disposition Data Collection Strategy Overview

Figure 2.6 presents the phased sampling strategy for the Site-wide Waste Disposition Evaluation Project. Much more analytical data are collected early in the project, during the decision-making stage as well as in the early stages of design. There were several geotechnical investigations to support WAC development, siting, and design, and there are many pre-design studies to evaluate the waste and construction material physical characteristics. There are also many more operation and maintenance monitoring requirements, along with verification sampling for QC during construction. But, as with the D&D project, there is routine environmental monitoring using analytical and field data to demonstrate compliance with ARARs and during construction and operation of the potential OSDC, as well as routine health and safety monitoring and sampling.

Future Plans and SAPs for Data Collection. The following submissions would be finalized following the waste disposition ROD for Ohio EPA review and approval/concurrence:

- OSDC Operational Plans
- WAC Attainment Plan.

These plans would provide guidelines for necessary data collection efforts during both the design and implementation/waste disposition stages to demonstrate ARARs compliance and WAC attainment according to the RODs. Additional project-specific plans and SAPs are also planned for development to collect project-level data according to the submissions listed above to ensure compliance with a potential OSDC WAC. The following is a list of these plans and SAPs that would be developed to support the process building and waste disposition projects and submitted for Ohio EPA review and approval/ concurrence, as applicable:

- Pre-Design Studies Plans

- WAC Attainment SAPs

- Integrated Remediation Design Packages

- Health & Safety Plans

- Regulatory Compliance Plans as required by the DFF&O to identify the basis and approach for compliance with ARARs/TBCs.

Consistent with this overall data collection strategy, the information collected for the waste disposition RI/FS is discussed below.

2.2.1 Waste Stream Characterization

The objectives for the characterization activities in the process buildings were to collect process equipment samples and provide characterization data to verify process knowledge assumptions, and support the refinement of waste volume projections and definition of waste types for the RI/FS. The characterization activities for the process buildings were outlined in the approved *Phase 1 Sampling and Analysis Plan for the Process Equipment Characterization in Support of the Sitewide Waste Disposition Evaluation Project at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2011c), which is referred to as the Process Equipment Characterization SAP. Samples were collected from primary process equipment (converters and compressors) and auxiliary equipment associated with other process gas systems (such as surge drums, instrument lines, etc.) in the three process buildings: X-333, X-330, and X-326. Following this data collection effort for the RI/FS, data collection under this plan continues in support of the follow-on remedial design/remedial action to support the determination of WAC compliance.

Prior to implementation of the Process Equipment Characterization SAP, an initial characterization effort consisted of collecting both a shell and composite barrier sample from five converters located at the following locations in X-326: 27-2-2, 27-3-2, 27-3-4, 25-1-2, and 25-2-2. Therefore, 10 samples were collected (five shell samples and five barrier samples). Two duplicate samples were collected, one from the shell of the converter at the 27-3-2 location and one from the barrier of the same converter. Each sample was analyzed for TCLP metals (arsenic, barium, cadmium, lead, selenium, and silver), mercury, copper, zinc, total beryllium, PCBs, SVOCs, VOCs, and radionuclides.

Mercury, silver, total uranium-233 (as a separate isotopic concentration rather than undifferentiated uranium-233/234), total beryllium, PCBs, SVOCs, and VOCs were not detected in any of the samples. The following bullets summarize the TCLP metal results from the initial characterization effort:

- Arsenic was detected in five of the 10 sample TCLP extracts at a range from 0.0179 to 0.313 mg/L; no concentration exceeded the 5.0 mg/L TCLP regulatory limit for arsenic. All of the detected concentrations were in the five barrier samples.

- Barium was detected in all 10 sample TCLP extracts at low concentrations (ranging from 0.0088 mg/L to 0.0340 mg/L) that did not exceed the TCLP regulatory limit of 100 mg/L for barium.

- Cadmium was detected in three of the sample TCLP extracts at concentrations (ranging from 0.0018 to 0.008 mg/L) that did not exceed the 1.0 mg/L TCLP regulatory limit for cadmium.

- Chromium was detected in eight of the 10 sample TCLP extracts at concentrations (ranging from 0.00776 to 0.8290 mg/L) that did not exceed the 5.0 mg/L TCLP regulatory limit for chromium.

- Lead was detected in five of the 10 sample TCLP extracts at concentrations (ranging from 0.0122 to 0.0918 mg/L) that did not exceed the 5.0 mg/L TCLP regulatory limit for lead.

- Selenium was detected in two of the 10 samples ranging from 0.0339 to 0.0494 mg/L, which did not exceed the TCLP regulatory limit for selenium.

- Zinc was detected in seven of the 10 sample TCLP extracts at concentrations ranging from 0.008 to 0.167 mg/L. There is no TCLP regulatory limit for comparison to these results.

Technetium-99 results from this initial characterization effort are provided in Table 2.3. These results confirm that the technetium-99 activity concentrations in the converter tubes are higher (generally two to three orders of magnitude higher) than those on the converter shells. While the converter tubes have higher activity concentrations, the average levels in process equipment will be less as they will be averaged over the total weight of the process equipment component. These samples conservatively estimate the average technetium-99 activities expected to be encountered in the converters.

Table 2.3. Technetium-99 Converter Initial Sample Results for PORTS

Converter Component ID	Shell Sample (pCi/g)	Tube Sample (pCi/g)
270302	186	2.72×10^5
270202	172	7.20×10^4
270304	77	1.59×10^5
250102	407	3.03×10^5
250202	198	3.05×10^4

ID = identification

The Process Equipment Characterization SAP included the collection of intrusive and nonintrusive samples and measurements. Intrusive characterization consisted of collecting physical samples by breaching the process gas system. Nonintrusive characterization consisted of collecting characterization data by using NDA techniques or surface swipes.

The sampling program design used both random and judgmental sampling techniques. In all cases, intrusive samples were collected at predetermined locations in the process equipment and analyzed for uranium isotopes and other constituents. Following collection of the samples, the individual pieces of equipment will be removed from the process line and moved to a low background area for nonintrusive NDA analyses.

The intrusive samples were of barrier material and shell coupons from converters, deposit material from the seal/seal cavity areas within the compressors, and coupons from process auxiliary equipment. Sample locations associated with the random sampling program were preselected using a random number selection process, allowing for an equal likelihood of selection. In contrast, the judgmental sampling applies the detailed process knowledge to pinpoint how the concentration of uranium isotope ratios and technetium-99 would change in a measurable manner based on system design and material makeup.

Results from the Process Equipment Characterization SAP sampling effort are similar to those from the initial characterization discussed above. The following bullets summarize the TCLP metals results for samples collected from converters in the X-326 Building per the Process Equipment Characterization SAP:

- Arsenic was detected in two of the four sample TCLP extracts with a range from 0.0041 to 2.36 mg/L; no concentration exceeded the 5.0 mg/L TCLP regulatory limit for arsenic.

- Barium was detected in all four sample TCLP extracts at low concentrations (ranging from 0.0124 to 0.115 mg/L) that did not exceed the TCLP regulatory limit of 100 mg/L for barium.

- Cadmium was detected in two of four sample TCLP extracts at concentrations (ranging from 0.0055 to 0.0058 mg/L) that did not exceed the 1.0 mg/L TCLP regulatory limit for cadmium.

- Chromium was detected in all four sample TCLP extracts at concentrations (ranging from 0.128 to 2.25 mg/L) that did not exceed the 5.0 mg/L TCLP regulatory limit for chromium.

- Lead was detected in all four sample TCLP extracts at concentrations (ranging from 0.0113 to 0.111 mg/L) that did not exceed the 5.0 mg/L TCLP regulatory limit for lead.

- Mercury was not detected in any TCLP sample extracts.

- Selenium was not detected in any TCLP sample extracts.

- Zinc was detected in all four sample TCLP extracts ranging from 0.00132 to 0.0066 mg/L.

Appendix A contains the laboratory data reported for these TCLP samples.

The current radiological results from the Process Equipment Characterization SAP sampling effort are provided in Table 2.4. These results represent the minimum and maximum values for selected radionuclides, based on the type of sample (either swipe sample or solid sample from the component [converter or compressor]) from the three process buildings.

Table 2.4. Process Equipment Sampling Results for the X-333, X-330, and X-326 Buildings at PORTS

	Converter Component Samples (pCi/g)		**Compressor Component Samples (pCi/g)**		**Compressor Swipe Samples (maximum) (pCi/sample)**
	Min	**Max**	**Min**	**Max**

Uranium-233/234	0.207	33,170	17.96	1,180	1,107,000
Uranium-235	0.053	1,007	0.745	36.5	38,870
Uranium-236	0.07	516.5	0.061	3.77	2,974
Uranium-238	0.052	623.3	0.105	12.62	3,210

Max = maximum detected value
Min = minimum detected value
NA = not applicable
ND = not detected above detection limit

These data indicate that for component samples, activity concentrations in converters are higher than those in the compressors. The data also indicate that technetium-99, uranium-233/234, and uranium-235 activities are typically greater in the higher end of the enrichment process (i.e., X-326 Building process equipment). The above table does not include results from deposits which had technetium-99, uranium-235, and uranium-238 maximum values of 2,020,000 pCi/g, 13,300 pCi/g, and 1,953 pCi/g, respectively (both technetium-99 and uranium-235 maximums occurred in X-326 while the uranium-238 maximum occurred in X-330). Appendix A contains the laboratory data reported for these process equipment samples.

Other analytes often detected in solid samples from the converters and compressors include chromium and lead. In all three process buildings, chromium ranged from 13.4 to 12,000 mg/kg in compressors and 9.1 to 707 mg/kg in converters. Lead results ranged from 1.9 to 444 mg/kg in compressors and 0.426 to 243 mg/kg in converters. These data indicate that chromium is higher in compressors than in converters, while lead is nearly the same for both pieces of equipment. The chromium and lead results were similar among the three process buildings. Appendix A contains the laboratory data reported for these samples.

2.2.2 Potential On-Site Disposal Study Area Characterization

Under this RI/FS, the Site-wide Waste Disposition Evaluation Project is evaluating four potential locations (Study Areas A, B, C, and D) (Figure 2.7) for a potential OSDC. Full development of a potential OSDC entails selecting a location and conceptualizing a design, which requires data on hydrogeologic and geochemical properties of soil and rock for subsurface flow and transport modeling and modeled WAC development. Geotechnical data are also needed to determine soil properties such as subsidence, compaction, and permeability.

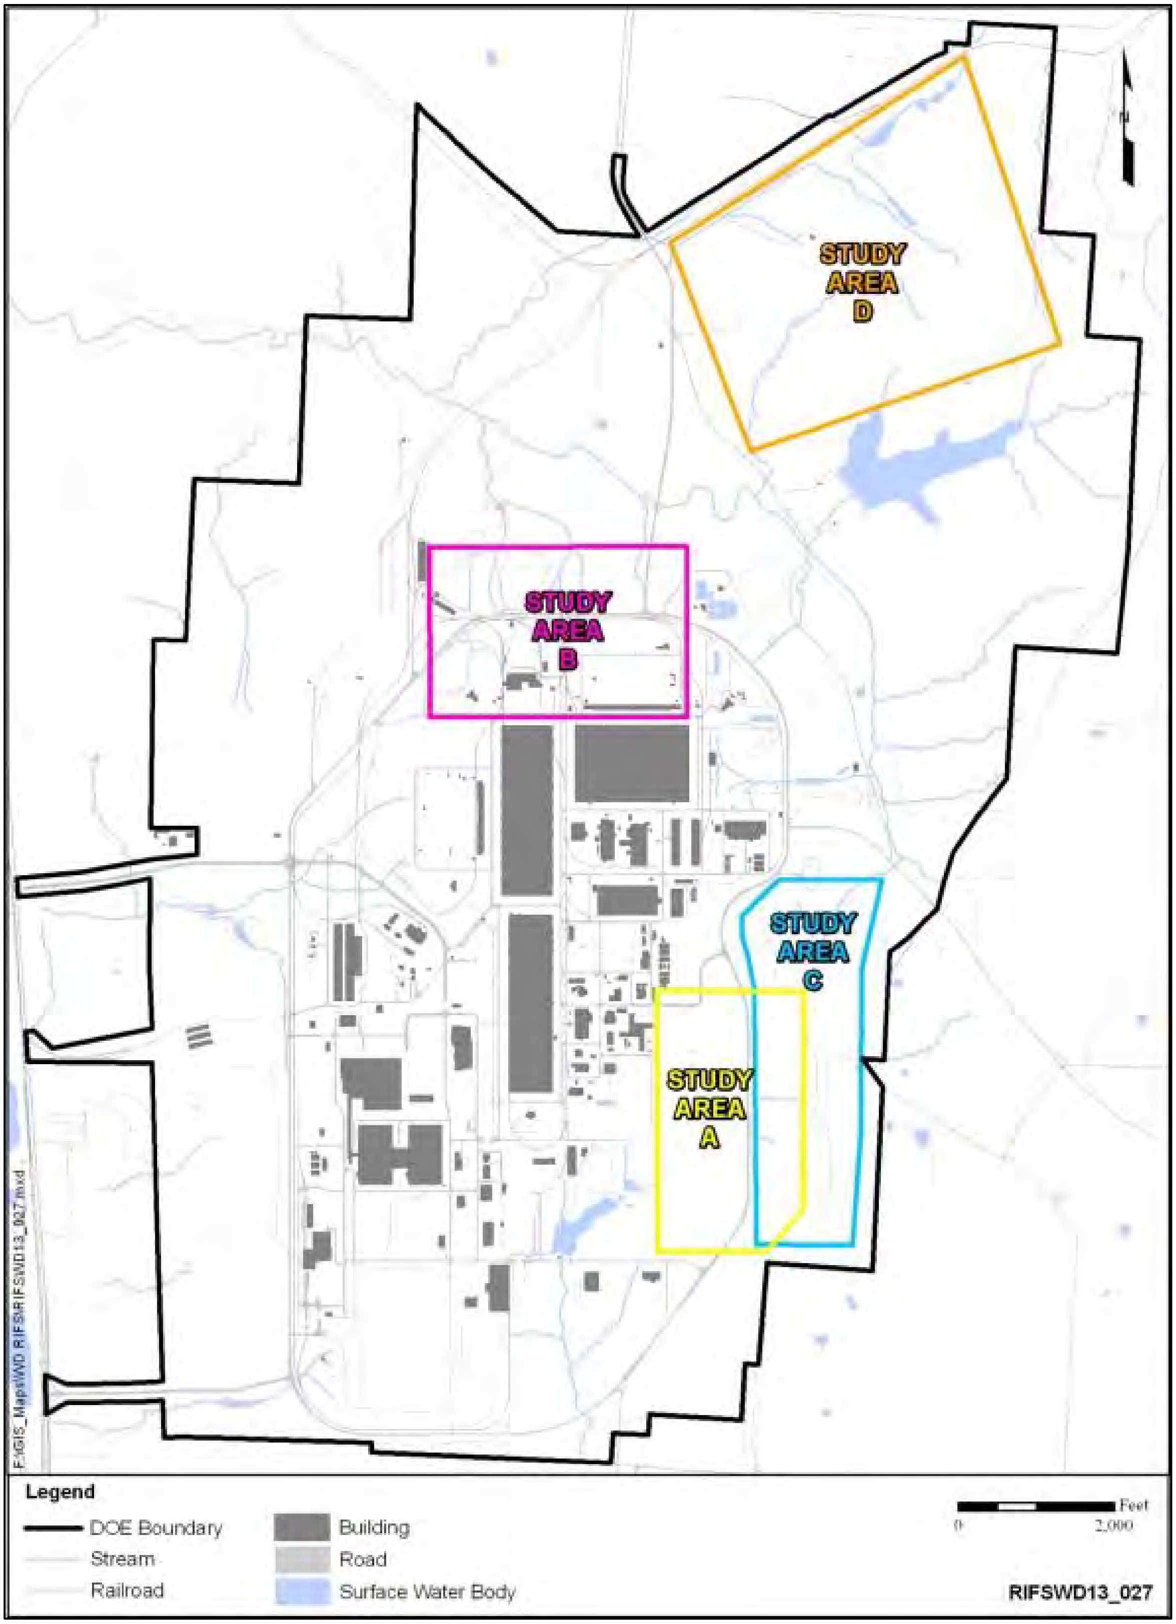

Figure 2.7. Locations of Four RI/FS Study Areas at PORTS

For these data collection efforts, several intrusive field methods were used to obtain the required geotechnical, geochemical, and analytical data, as outlined in *Geotechnical Sampling and Analysis Plan for the Sitewide Waste Disposition Evaluation Project at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2011a), referred to as the Geotechnical SAP, and the *Supplemental Geotechnical Sampling and Analysis Plan for the Sitewide Waste Disposition Evaluation Project at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2012c). These methods include, but are not limited to, cone penetration testing (CPT), drilling in both unconsolidated and bedrock formations to collect soil samples for geotechnical and geochemical testing, and installation of monitoring wells and piezometers.

The Geotechnical SAP was written to ensure that the field investigation and sampling were performed in a technically acceptable manner. The specific types of data collected included the following:

- Hydrogeologic data (depth to groundwater, vertical permeability), where already available data were insufficient for evaluating locations for a potential OSDC (primarily Study Areas A, C, and D)

- Geochemical data (contaminant adsorption coefficients, fraction of organic carbon in soil) to support modeling for development of modeled WAC (all study areas)

- Geotechnical and analytical data from the four RI/FS study areas being evaluated in the FS

- Changes made in the field to add investigation of nearby surface water streams and installation of test pits (Study Area D only).

An evaluation of the characteristics of the soils, geology, and groundwater pertinent for the proper siting, construction, operation, and monitoring of a potential OSDC was conducted. Important site-specific characteristics required by *Ohio Administrative Code (OAC)* 3745-27-06(C)(3) include the following:

Soil and bedrock characteristics
- Soil or rock type
- Color
- Moisture content
- Layering or interbedding
- Weathering
- Fracturing or jointing
- Mineral content
- Thickness
- Horizontal extent
- Depth and elevation.

Groundwater characteristics
- Uppermost aquifer system and significant zone of saturation
- Flow direction and rate
- Hydraulic conductivity
- Interconnection within upper aquifer system and significant zone of saturation
- Groundwater level elevation
- Temporal fluctuations
- Recharge and discharge

- Groundwater yield
- Groundwater chemistry.

In order to establish compliance with ARARs such as the Ohio solid waste disposal facility siting requirements for adequate investigation (*OAC* 3745-27-06[C][3]), hydrogeologic and geotechnical field investigation activities have been completed. Much information on the geology and groundwater characteristics of PORTS is available from previous investigations at PORTS. The recent efforts, combined with the historical investigation data, provide information that is used to identify and characterize the geology and hydrogeology sufficiently to allow Ohio EPA to determine the suitability of the site for solid waste disposal along with compliance with ARARs. Table 2.5 provides a crosswalk of the requirements for a hydrogeologic investigation report pursuant to *OAC* 3745-27-06(C)(3) and appropriate sections of this RI/FS report.

Table 2.5. Crosswalk between Requirements of *OAC* 3745-27-06(C)(3) and this RI/FS Report

Requirement (*OAC* 3745-27-06)	Content	RI/FS Report Section that Corresponds to the Requirement
	Suitability of the Site for Solid Waste Disposal	
(C)(3)(a)(i)	Identification and characterization of the hydrogeology of the uppermost aquifer system and all stratigraphic units that exist above the uppermost aquifer system	Section 2.2.2.1; Appendix D

(C)(3)(g)	Description of how the subsurface investigation was conducted	Section 2

OAC = Ohio Administrative Code
RI/FS = Remedial Investigation/Feasibility Study
USCS = Unified Soil Classification System

Specifically, the main targets of the recent field efforts are primarily related to data gaps at Study Area D as follows:

1. Top of competent bedrock determination

   This information is required per *OAC* 3745-27-06(C)(3)(d)(i)(d) to provide depth and elevation of the consolidated stratigraphic units. Installation of borings and piezometers is complete, and well logs have been evaluated. The depth to competent bedrock (Cuyahoga Formation) is discussed in this section and in Appendix D.

2. Sandstone layers at approximate elevation 720 ft above mean sea level (AMSL)

   This information is required per *OAC* 3745-27-06(C)(3)(d)(i)(a) – (e) to provide a description of these consolidated stratigraphic units encountered in the upper Cuyahoga Formation. Installation of borings and piezometers within and near the proposed footprint of a potential OSDC at Study Area D is complete, and well logs have been evaluated. The characteristics of these multiple, thin (less than 1.5 ft thick) sandstone layers are discussed in this section and in Appendix D.

3. Sandstone layer at approximate elevation 680 ft AMSL

   Establishing characteristics such as elevation, recharge, moisture content, fracturing, etc. of this sandstone layer within the upper Cuyahoga Formation is required per *OAC* 3745-27-06(C)(d)(i)(a) – (e) to provide a description and analysis of this unit. Installation of borings, piezometers, and test pits within the proposed footprint of a potential OSDC at Study Area D is complete, and well logs have been evaluated. The characteristics of this continuous, 2-ft-thick sandstone layer are discussed in this section and in Appendix D.

4. Saturated zone (occurring near piezometers WD-PZ09C and WD-PZ12C) in the southern portion of Study Area D

   This information is required per *OAC* 3745-27-06(C)(3)(d)(iv)(a) – (d) to provide a description of this significant zone of saturation, including groundwater yield. Packer tests have been completed at WD-PZ09C and WD-PZ12C to isolate the permeable saturated zones and determine groundwater yield. Additionally, the borings were advanced an additional 5 ft and monitored for depth to groundwater. A description of this saturated zone is provided in this section and in Appendix D.

5. Saturated zone (occurring near piezometer WD-PZ14C) in the northern portion of Study Area D

   This information is required per *OAC* 3745-27-06(C)(3)(d)(iv)(a) – (d) to provide a description of this significant zone of saturation, including groundwater yield. Additional borings have been drilled (WD-SB-53 and WD-SB-57) and left open as piezometers (WD-PZ17C and WD-PZ16C) for monitoring depth to groundwater. A description of this saturated zone is presented in this section and in Appendix D.

Remaining data from all borings, piezometers, monitoring wells, and test pits that were to address the above targeted information gaps are presented in this waste disposition RI/FS report. Information presented herein provides sufficient characterization of the geology and hydrogeology in order to comply with *OAC* 3745-27-06(C)(3)(a) – (g) as noted in Table 2.4.

Investigation activities used standard industry practices consistent with Ohio EPA procedures and protocols in the *Technical Guidance Manual for Hydrogeologic Investigations and Ground Water Monitoring (TGM)* (Ohio EPA 2011).

2.2.2.1 Hydrogeologic investigation

The overall hydrogeologic conditions and groundwater flow at PORTS are reasonably well understood. However, for some of the RI/FS study areas located on the periphery of the DOE property, particularly Study Areas C and D, additional information to verify depth to groundwater and collection of samples for permeability testing were needed.

Prior to installation of piezometers or monitoring wells, soil borings were advanced to collect samples for lithologic logging and/or laboratory analyses. Drilling methods included the use of hollow-stem auger, mud-rotary, and air-rotary methods. Subsurface soil/rock samples were collected from borings in accordance with the Geotechnical SAP. Split-spoon and Shelby tube samples were collected at regular intervals throughout the depth of the unconsolidated material. Once bedrock was reached, rock coring was used continuously until the bottom depth of the boring was reached. The rock core was visually examined for evidence of fracturing and weathering (to distinguish between natural fractures and mechanical breaks from drilling/coring).

Depth to groundwater needed to be determined at Study Areas A, C, and D (depth-to-groundwater data are sufficient at Study Area B, which has 15 monitoring wells within its boundary). Twenty-seven piezometers and seven monitoring wells were installed in the three study areas (Figure 2.8 and Table 2.6). Appendix B contains the boring and monitoring well logs.

Using a hollow-stem auger rig, three piezometers were installed within the unconsolidated Minford/Gallia members in Study Area A. These piezometers were screened at the contact of the Minford or Gallia members with the underlying bedrock.

Seven monitoring wells were installed for long-term monitoring in the Berea sandstone. Two of these monitoring wells were installed along the eastern DOE property boundary near Study Area C, and five were installed in Study Area D.

Groundwater level measurements were collected as part of the RI to provide hydraulic data to support the physical setting of the location and for developing models for calculating modeled WAC for a potential OSDC. Beginning in June 2011, water levels were periodically measured in the RI/FS wells and selected pre-existing wells. These data are primarily used to determine the direction of groundwater flow and depth of the water table surface in the various hydrogeologic units. All groundwater elevation data for the monitoring wells and piezometers installed to support this RI/FS are reported in Appendix A. Hydrographs for the monitoring wells and piezometers installed for this project also are provided in Appendix A.

Hydrogeologic Investigation Specific to Study Areas A and C

Four soil borings at Study Area C were completed as piezometers within the Cuyahoga Formation and Sunbury shale to determine if the shale formations were saturated and, if so, to collect information on depth to groundwater within the shale. The Cuyahoga/Sunbury piezometers within Study Area C were completed with a 5-ft screen ranging from an approximate elevation of 620 to 630 ft AMSL. In addition to these piezometers, which were drilled with mud-rotary methods, temporary piezometers (drilled dry with air-rotary methods) were placed adjacent to Cuyahoga/Sunbury piezometers WD-PZ04C, WD-PZ06C, and WD-PZ07C at Study Area C. This was done to verify that no water-bearing fractures had been encountered in the shale (which may have not been noticed using mud-rotary methods).

The Cuyahoga/Sunbury piezometers (as well as the temporary air-rotary-drilled borings) at Study Area C sometimes have too little water to allow a water level measurement. Only piezometers WD-PZ04C and WD-PZ05C show significant water level fluctuations with 22.3 ft and 6.2 ft, respectively. The large fluctuations in water levels in WD-PZ04C suggest this piezometer may be in hydraulic connection with a fracture/joint that is also in connection with the regolith zone. Piezometers WD-PZ06C and WD-PZ07C, on the other hand, exhibit water level fluctuations of only 1.1 ft and 0.5 ft respectively. The three air-rotary borings adjacent to WD-PZ04C, WD-PZ06C, and WD-PZ07C never had sufficient water to allow a depth-to-water measurement.

Using a hollow-stem auger rig, three piezometers were installed within the unconsolidated Minford/Gallia members in Study Area A, which overlaps with the western portion of Study Area C. These piezometers were screened at the contact of the Minford or Gallia members with the underlying bedrock. Water level fluctuations in the three Gallia piezometers are shown in Figure 2.9. The Gallia represents the uppermost aquifer system over most of Study Area A.

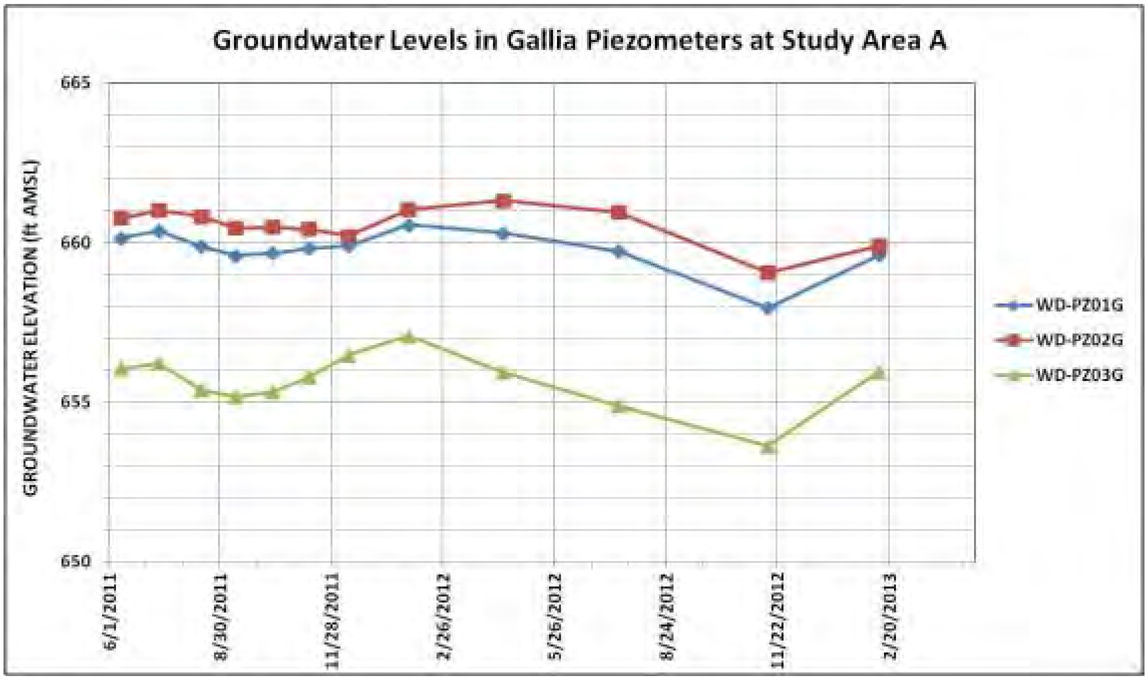

Figure 2.9. Hydrograph for the Gallia at Study Area A

The Berea sandstone, the uppermost aquifer system beneath Study Area C, is a regional confined aquifer with a potentiometric surface approximately 20 to 25 ft above the top of the aquifer. Figure 2.10 shows a comparison of groundwater levels measured in the Cuyahoga to those measured in the Berea sandstone at Study Area C. The Berea exhibits very little seasonal fluctuation. The potentiometric level of the Berea sandstone is also typically higher than the measured water levels in the Cuyahoga piezometers at Study Area C, indicating an upward hydraulic gradient. However, on two occasions, the water level in at least one Cuyahoga piezometer was higher than the potentiometric surface of the Berea, suggesting temporary downward gradients.

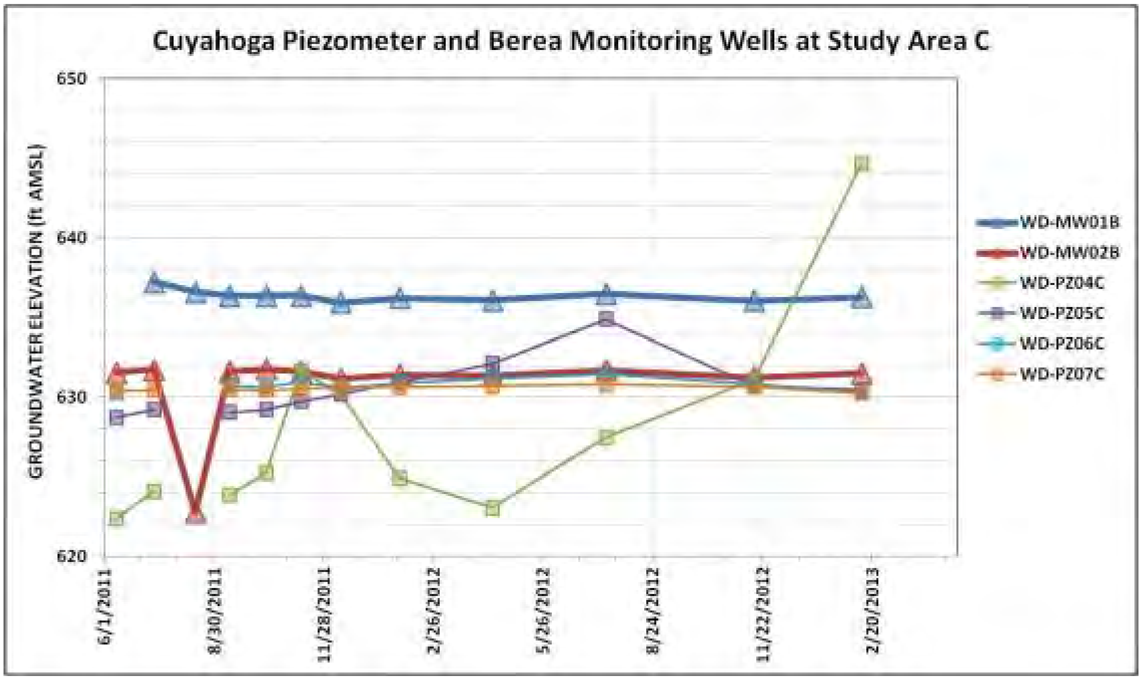

Figure 2.10. Hydrograph comparing Cuyahoga and Berea Water Elevations at Study Area C

Hydrogeologic Investigation Specific to Study Area B
The hydrogeology of Study Area B, which has 15 monitoring wells located within the study area boundary, is well understood. The X-344 and X-533 complexes, which cover most of Study Area B, were investigated during the Quadrant IV RFI conducted in 1992-1993 (Phase I) and 1994 (Phase II) (DOE 1996d). Several shallow and deep soil borings were installed at each complex for the collection of soil samples. In addition, several shallow borings were installed following D&D of the X-533 complex. In Study Area B, groundwater is monitored at the X-344C Former Hydrogen Fluoride Storage Building and the X-533 Former Switchyard Complex routinely as part of the Integrated Groundwater Monitoring Program. No additional hydrogeologic investigation was conducted as part of this waste disposition project.

Hydrogeologic Investigation Specific to Study Area D
Twenty piezometers were completed within the Cuyahoga Formation at Study Area D to determine if the shale and interbedded sandstone units were saturated and, if so, to collect information on depth to groundwater within the Cuyahoga. The Cuyahoga piezometers installed at Study Area D were initially completed with an open borehole completion because drilling at Study Area C determined the Cuyahoga to be competent enough to support an open borehole construction. Most of the piezometers were later converted to standard cased piezometers with 10-ft screens.

The saturated zones occur either : (1) where a 2-ft-thick sandstone layer and a 0.5-ft-thick sandstone layer (at an approximate elevation of 680 ft AMSL) is saturated; (2) where several thin, interbedded sandstones occur near an elevation of 720 ft AMSL; or (3) where fractures/joints contain groundwater.

Using air rotary drilling methods (dry drilling), several bedrock piezometers were initially installed at Study Area D. At Study Area D, a 2-ft-thick sandstone layer was recognized in several borings at an elevation of approximately 680 ft AMSL within the Cuyahoga Formation. This layer can be combined with another 0.4-ft-thick sandstone layer which occurs approximately 2 ft beneath the thicker layer. These two sandstone layers and the intervening 2-ft shale interval are referred to as the "680-ft sandstone zone." This sandstone zone is continuous across Study Area D except where it has been removed by erosion to the west and north. The 680-ft sandstone in the Cuyahoga Formation occurs approximately 55 to 60 ft above the Berea sandstone which represents the uppermost aquifer system in this area. Figure 2.11 shows the structure of the 680-ft sandstone zone and indicates it follows the regional dip to the east-southeast.

Figures 2.12 through 2.18 show the water level response following drilling at seven of the bedrock piezometers. The upper sandstone layer in the 680-ft sandstone zone is shown on these figures. These figures depict the water levels while the piezometers were open hole borings plus the water levels after being screened across the 680-ft sandstone zone. Also depicted on these figures is the approximate depth of weathering, based on a coloration change in the rock core. WD-PZ08C and WD-PZ10C, which were drilled approximately to the depth of the 2-ft-thick sandstone layer, were initially dry, or had insufficient water for measurement. WD-PZ08C was dry until it was drilled to a depth approximately 10 ft below the 680-ft sandstone. This saturation may be from bedding plane partings associated with the lower 0.5-ft-thick sandstone layer in the 680-ft sandstone zone.

The water level in WD-PZ12C was approximately 720 ft AMSL until the boring was extended through the 680-ft sandstone. After being extended, the groundwater level stabilized at approximately 684 ft AMSL. The initial water level, at an approximate elevation of 720 ft AMSL, appears to be related to thin, mostly discontinuous sandstone layers in the upper Cuyahoga Formation. This upper zone of interbedded sandstones is referred to as the "720-ft sandstone lens zone." The thickness of the individual significant sandstone lenses in this zone range from 0.3 ft to 1.5 ft with an average of 0.5 ft. Several borings intersected multiple sandstone layers in this zone. The individual sandstone layers that comprise the 720-ft sandstone facies are difficult to correlate from boring to boring and do not appear to be continuous across Study Area D. Saturated conditions within the 720-ft sandstone facies appear to be limited or localized. Appendix D provides additional discussion on the hydrogeology of Study Area D.

At piezometer WD-PZ14C, on the northern side of the hill in Study Area D, the water level is at an elevation of approximately 670 ft AMSL. This elevation is below the occurrence of the 680-ft sandstone zone described above. This area appears to be a localized saturated zone within the Cuyahoga shale that is not continuous to the south in areas of higher topography as observed in WD-PZ16C and WD-PZ17C. A review of historical aerial photographs shows that WD-PZ14C is located within the area of a backfilled pond that was associated with the activities in a former borrow area. This piezometer has an open-borehole design with the surface casing set in the top of competent bedrock.

Hydraulic testing was performed in several of the Cuyahoga piezometers in Study Area D to determine yield of the piezometers and hydraulic conductivity of the 680-ft sandstone layer, and to investigate the connectivity of the saturated zones in the Cuyahoga Formation with the deeper Berea sandstone.

The degree of hydraulic interconnectedness between the Berea and Cuyahoga Formations was investigated by pumping the Berea Formation and monitoring the response, or absence of response, in the Cuyahoga Formation. Tests were conducted in each of the four Berea wells (WD-MW03B, WD-MW04B, WD-MW05B, and WD-MW06B) while water levels were monitored in the Cuyahoga piezometer paired with the Berea well.

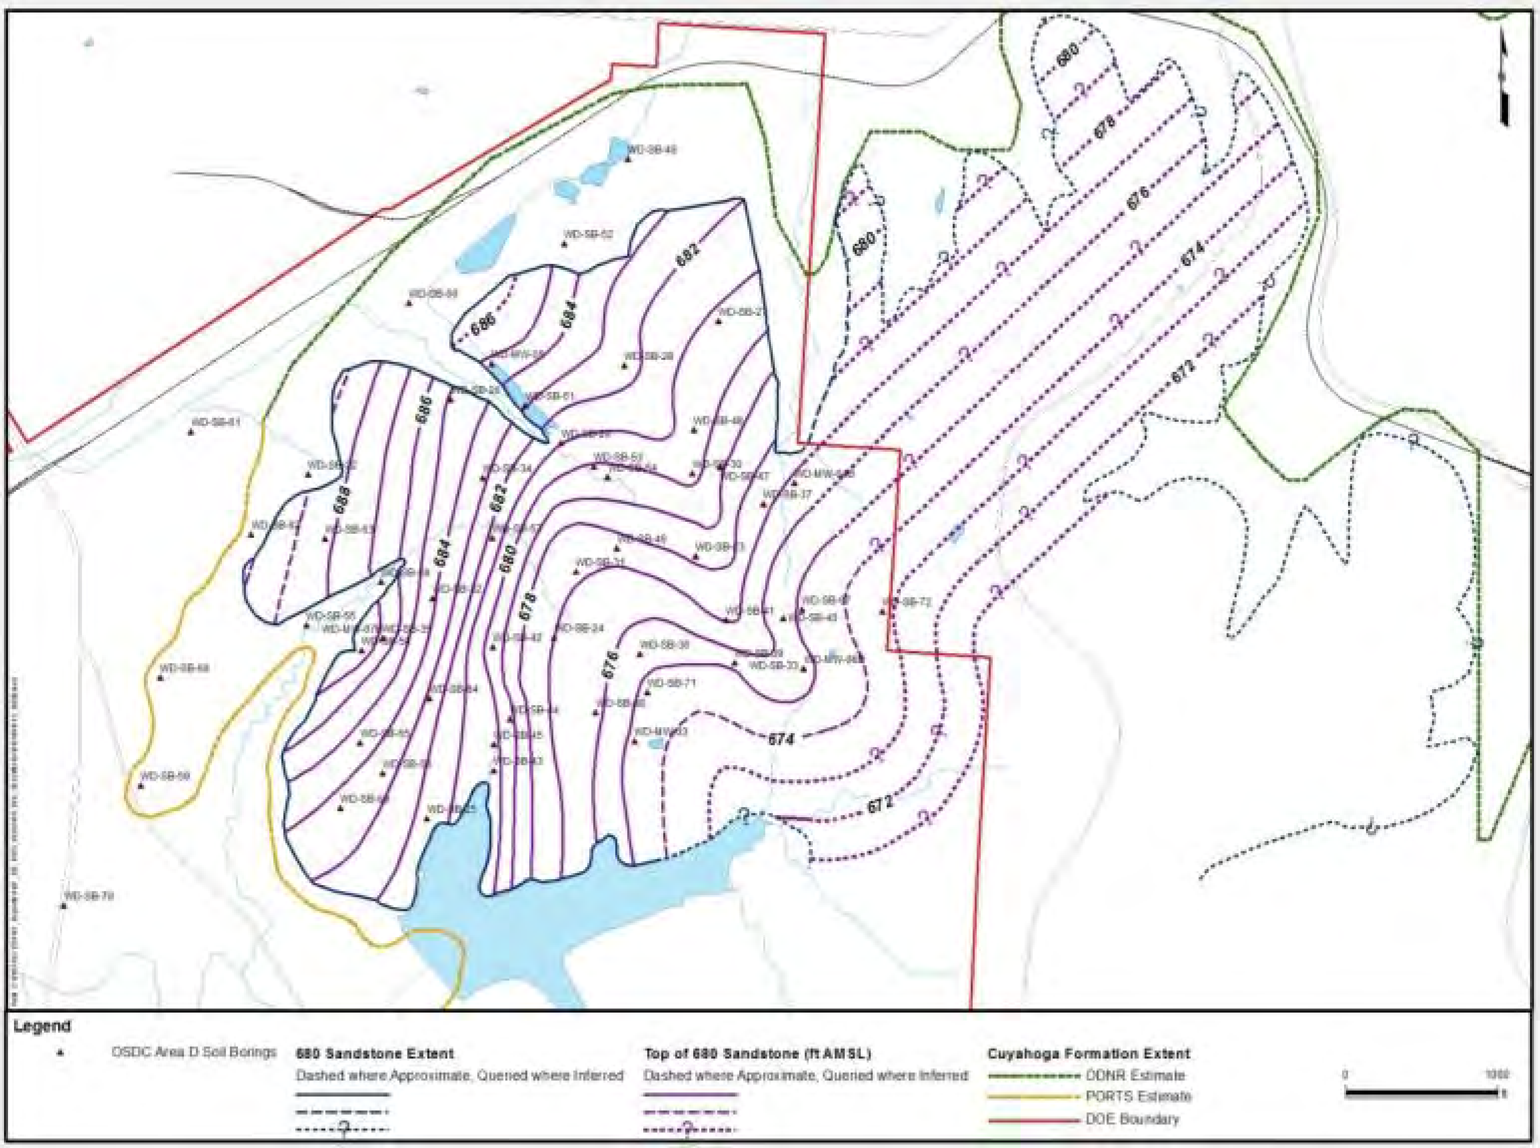

Figure 2.11. Elevation of the Top of the 680-ft Sandstone at Study Area D

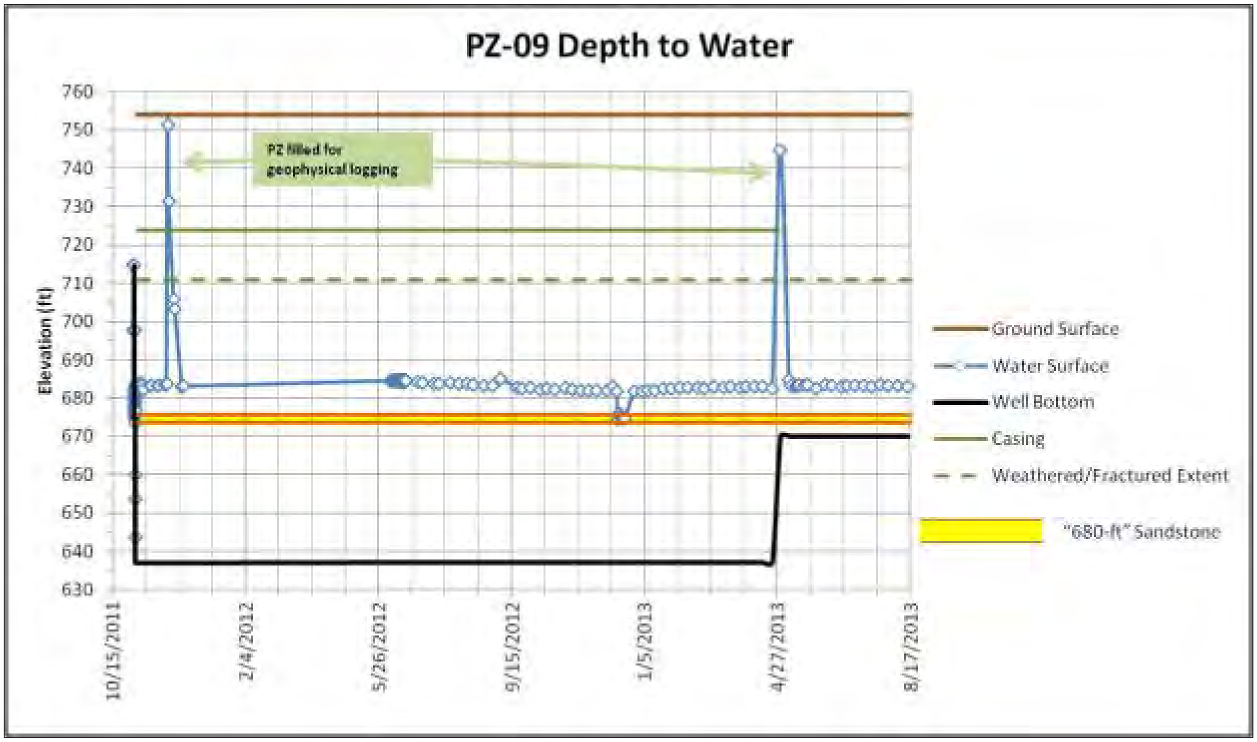

Figure 2.13. Water Level following Installation of WD-PZ09C at PORTS

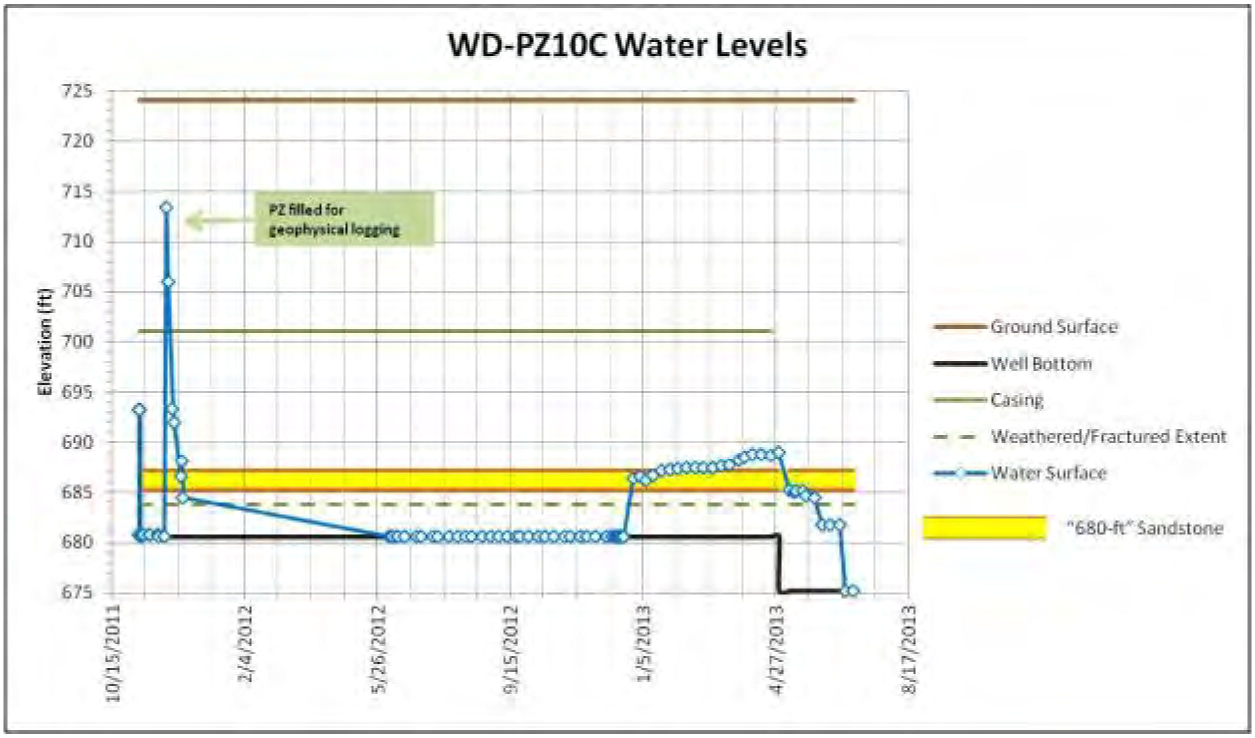

Figure 2.14. Water Level following Installation of WD-PZ10C at PORTS

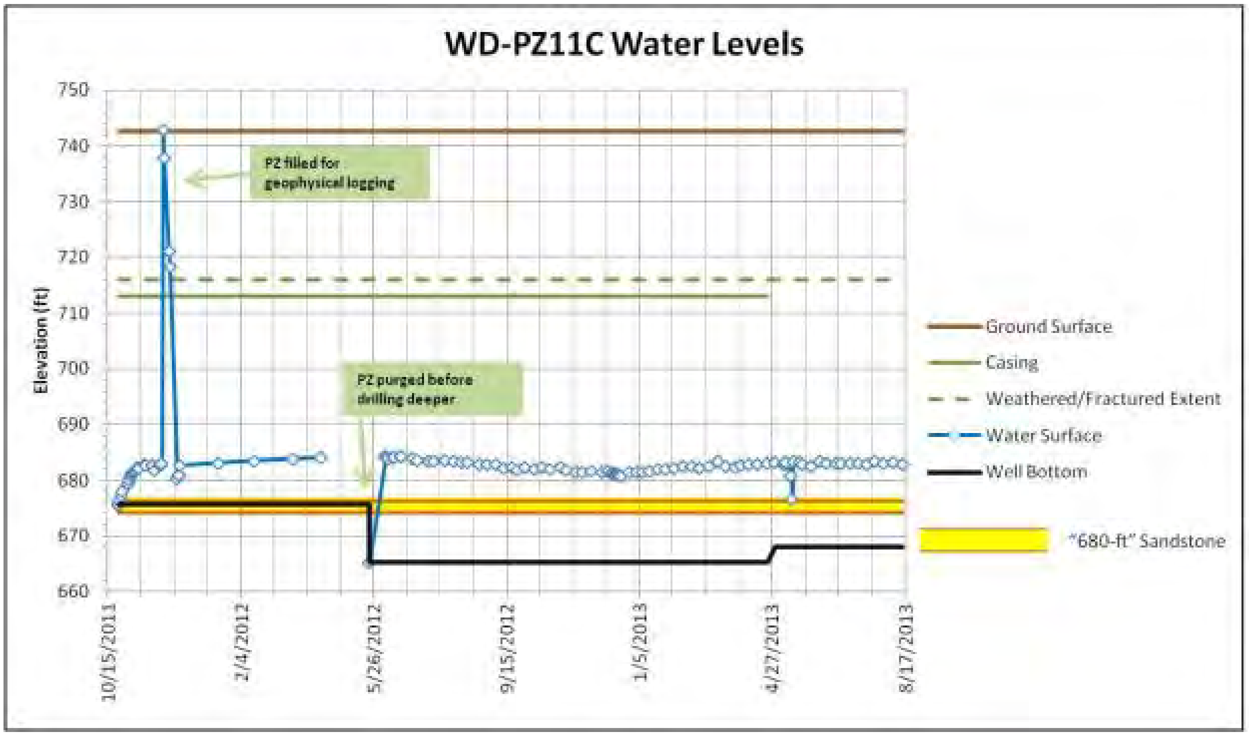

Figure 2.15. Water Level following Installation of WD-PZ11C at PORTS

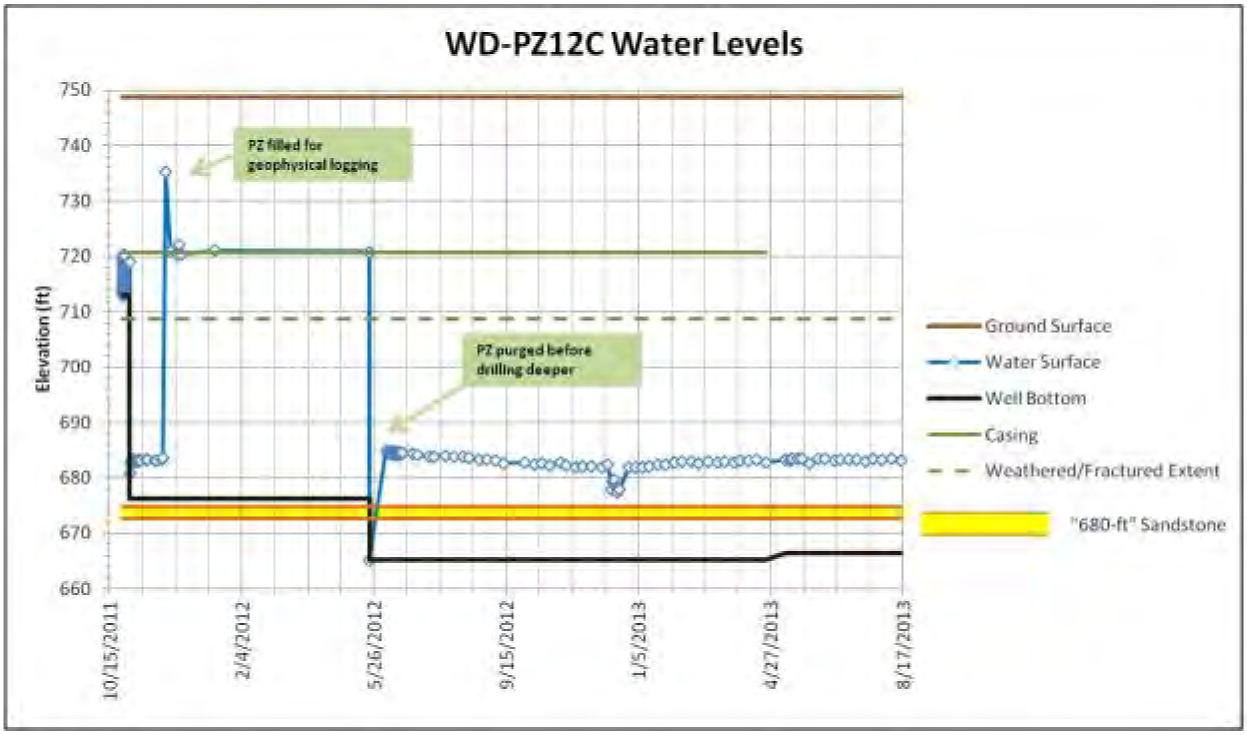

Figure 2.16. Water Level following Installation of WD-PZ12C at PORTS

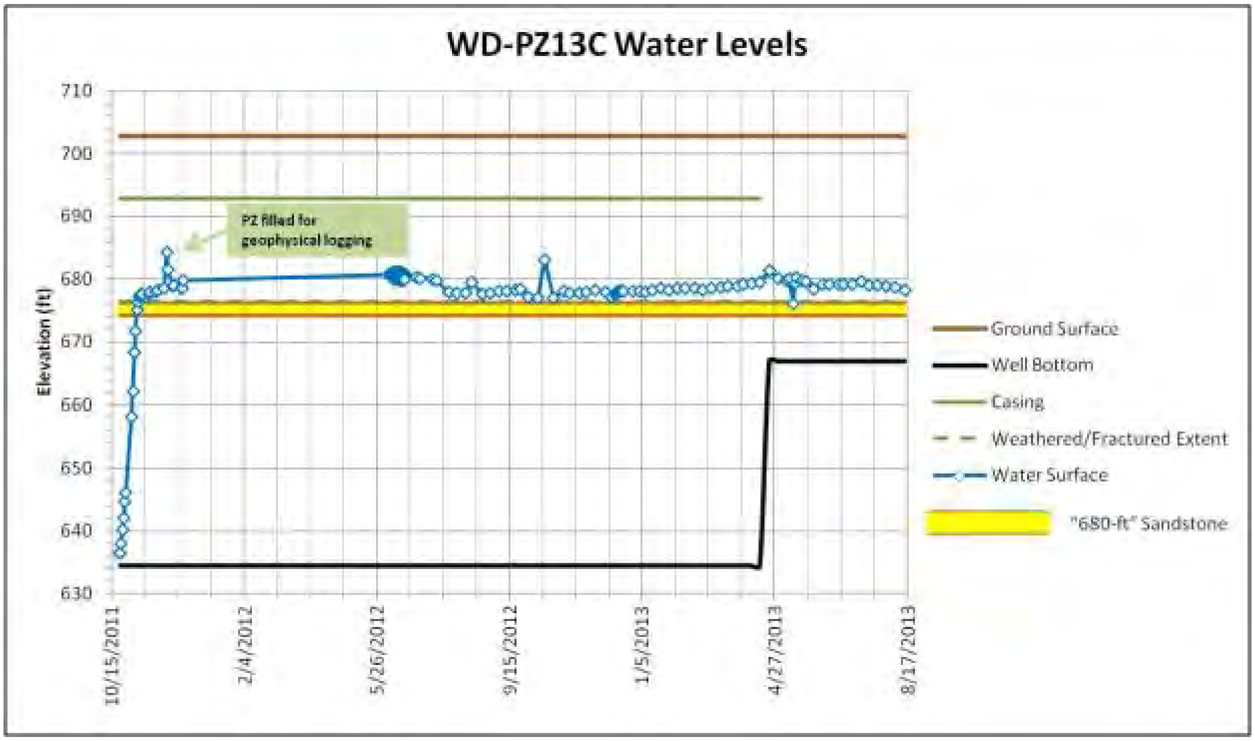

Figure 2.17. Water Level following Installation of WD-PZ13C at PORTS

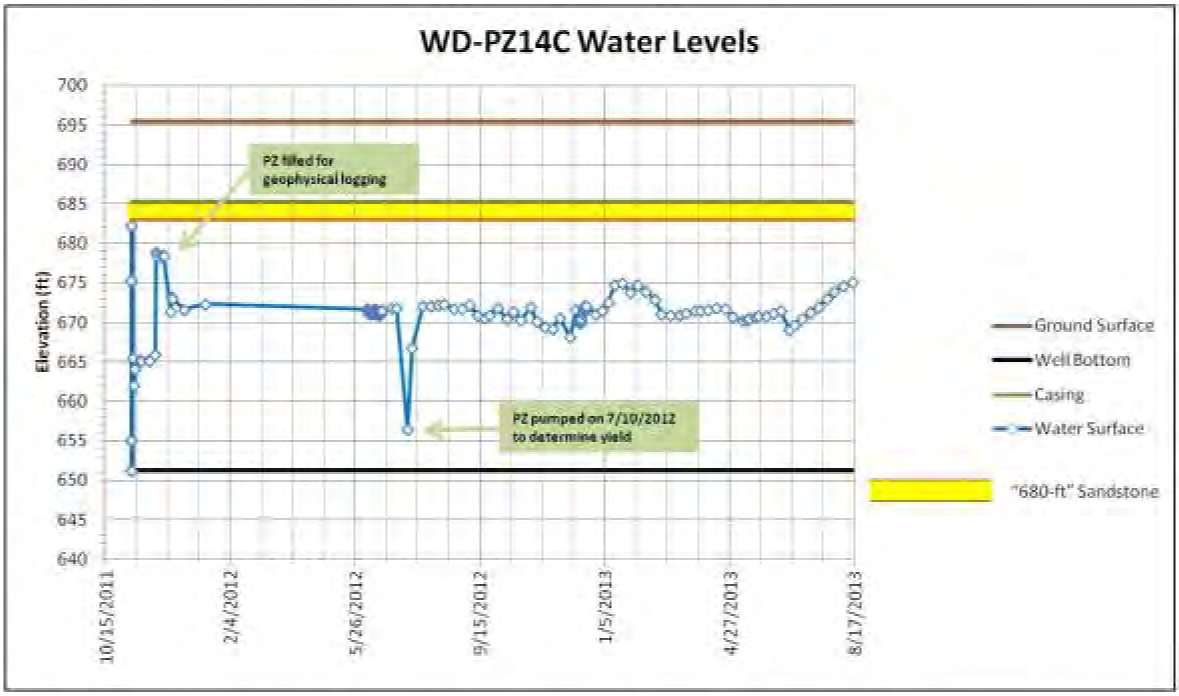

Figure 2.18. Water Level following Installation of WD-PZ14C at PORTS

Each test was started by pumping the Berea well at 0.1 gpm. If the Berea well yield was sufficient (i.e., > 0.1 gpm), the test progressed by selecting additional pumping rates of increasing magnitude. If the Berea well yield was insufficient (i.e., <0.1 gpm), the Berea well was pumped dry and water level recovery was recorded. Recovery data were recorded as feet of recovery per time. The values were then converted into volume per time to characterize the yield of the well.

To determine the hydraulic properties for the Cuyahoga Formation, testing consisted of yield tests and long-term constant rate tests. Where present, water levels were monitored in nearby Cuyahoga piezometers and/or bedrock borings (open boreholes) to provide additional data for the hydraulic property evaluation.

Yield tests were initiated at the following six piezometers by placing a pump approximately 2 ft above the borehole bottom and pumping the entire borehole (without the use of packers):

- Pumped WD-PZ11C and monitored WD MW06B
- Pumped WD-PZ13C and monitored WW MW04B
- Pumped WD-PZ14C and monitored WD MW05B
- Pumped WD-PZ15C and monitored SB67
- Pumped WD-PZ16C and monitored SB57
- Pumped WD-PZ17C and monitored SB53, SB54.

Each open borehole piezometer test started with an initial pumping rate of 0.1 gpm and was intended to progress by selecting three additional pumping rates of increasing magnitude. Pumping rates progressed only if the Cuyahoga piezometer could sustain a 0.1 gpm discharge rate with stable drawdown over 1 hour. The flow rate at each subsequent pumping rate was selected based on the drawdown measured during the previous pumping step. The goal was to determine if the piezometer should receive subsequent testing of isolated zones. The nearby Berea well was monitored during testing of WD-PZ11C, WD-PZ13C, and WD-PZ14C to detect any evidence of hydraulic communication between the Cuyahoga and Berea Formations. In the case of WD-PZ15C, WD-PZ16C, and WD-PZ17C, the nearby Cuyahoga borings SB67, SB57, and SB53/SB54 were monitored in the expectation of detecting a hydraulic response that would provide an additional method for estimating a value for hydraulic conductivity for the Cuyahoga Formation.

Testing of isolated zones within the Cuyahoga piezometers was initiated at open boreholes that could sustain a 0.1 gpm discharge rate with stable drawdown over 1 hour. A pneumatic packer assembly was configured so the target zone could be isolated. The selected pumping zones were:

- WD-PZ09C: 679 to 671 ft AMSL (2-ft sandstone layer)
- WD-PZ09C: 671 to 636 ft AMSL (possible saturated zone below 2-ft sandstone layer)
- WD-PZ12C: 749 to 709 ft AMSL (saturated zone above 2-ft sandstone layer)
- WD-PZ12C: 710 to 679 ft AMSL (possible saturated zone above 2-ft sandstone layer)
- WD-PZ12C: 712 to 681 ft AMSL (possible saturated zone above 2-ft sandstone layer)
- WD-PZ12C: 678 to 663 ft AMSL (2-ft sandstone layer).

Each test started with an initial pumping rate of 0.1 gpm and was intended to progress by selecting three additional rates of increasing magnitude. Pumping rates progressed only if the isolated zone could sustain a 0.1 gpm discharge rate with stable drawdown over 1 hour. Each subsequent pumping rate was selected based on the drawdown measured during the previous pumping step. The goal was to have the third pumping rate match the maximum pumping rate sustainable during a long-term, constant rate test. If a steady-state flow rate of 0.1 gpm could not be maintained, the zone was pumped dry and the recovery of the well was recorded. These data were recorded as feet of recovery per time. The values were converted into volume per time to characterize the yield of the well.

A long-term constant rate test was planned for each isolated zone that could sustain a 0.1 gpm discharge rate with stable drawdown. The goal was to collect data allowing an estimate of the hydraulic transmissivity and storativity within the Cuyahoga Formation. The selected pumping zones were the 680-ft sandstone layer in WD-PZ09C and WD-PZ12C. Each test was terminated after 48 hours. A technical memorandum of the hydraulic testing is provided in Appendix C.

Only two piezometers yielded greater than 0.1 gpm. WD-PZ09C and WD-PZ12C yielded 0.6 gpm and 1.2 gpm, respectively, while yields at WD-PZ11C, WD-PZ13C, WD-PZ14C, WD-PZ15C, WD-PZ16C, and WD-PZ17C were four orders of magnitude less (ranging from 0.0007 gpm to 0.05 gpm). WD-PZ09C and WD-PZ12C also exhibited high barometric efficiency (approximately 90 percent), which suggests the tested zone is confined to a high degree (barometric efficiency is related to the magnitude of water level response due to changes in barometric pressure). The hydraulic conductivity of the 680-ft sandstone layer, determined from preliminary evaluation of constant rate testing in WD-PZ09C and WD-PZ12C, was estimated to be in the range of 40 to 50 ft/day. This conductivity is higher than would be expected, based on literature values for fractured sandstone. The limited response to pumping observed in other nearby piezometers would also suggest a lower hydraulic conductivity. Hydraulic conductivity in piezometers WD-PZ15C, WD-PZ16C, and WD-PZ17C was estimated to be much lower, ranging from 0.001 to 0.004 ft/day, but this may have been related to formation damage (skin effect) during drilling and poor piezometer development due to little water being produced from the formation. These piezometers also exhibited lower barometric efficiencies. In addition, testing indicated no hydraulic communication between the Cuyahoga Formation and the Berea sandstone.

Eight bedrock cores were also collected (five from the Cuyahoga Formation, two from the Sunbury, and one from the Berea) at Study Area D for permeability (saturated vertical hydraulic conductivity) testing. Two of the Cuyahoga cores were from the 680-ft sandstone. Results are provided in Section 2.2.2.2.

At Study Area D, the water levels measured in the Cuyahoga piezometers are approximately 50 to 60 ft above the potentiometric level of the Berea at locations WD-MW04B and WD-MW06B and 80 ft higher at WD-MW03B. At WD-MW05B, the Cuyahoga water level in the adjacent piezometer (WD-PZ14C) is approximately 30 ft above the Berea potentiometric level.

Figures 2.19 and 2.20 show possible groundwater flow directions for the 680-ft sandstone unit. (Figure 2.19 shows current conditions, and Figure 2.20 shows potential future conditions after the water level in X-611B is lowered.) A typical potentiometric map is not provided because the water level and yield data suggest there may be limited hydraulic connection across the entire area. For the future condition shown in Figure 2.20, it is assumed the water level in X-611B is 660 ft AMSL or lower. Throughout the study period, the depth to the potentiometric surface as measured in the piezometers and monitoring wells was relatively consistent. The southern area near WD-PZ09C and WD-PZ12C appears to be influenced by interconnected fractures providing recharge and bedding plane partings and fractures within the 680-ft sandstone that allow greater transmissivity. During the wetter times of the year, recharge occurs where the 680-ft sandstone is closer to the surface and stress-relief fractures provide a pathway for water in the regolith to recharge the upper bedrock. This is most evident near WD-PZ16C which often has the highest water levels in the 680-ft sandstone. WD-PZ16C lies in a valley with the sandstone subcropping beneath the regolith just below ground surface. The hydraulic gradient in the center of the area is very small and WD-PZ23C is slow to stabilize. Groundwater moves towards areas of lower hydraulic head along valleys where the sandstone outcrops and also towards the east-southeast (in a structurally down-dip direction).

There is a localized area of saturation associated with the 720-ft sandstone lenses in the vicinity of WD-SB-40 and WD-PZ15C. The sandstone lenses receive recharge where they outcrop, or subcrop beneath the regolith (within the stream valley that WD-PZ15C is located within), or where fractures occur. The groundwater then moves laterally along the sandstone lens (or along bedding plane partings) and may re-emerge along the hillside in an ephemeral seep. None of the other open-hole piezometers had a groundwater elevation that coincided with the 720-ft sandstone zone.

Borehole geophysical tools were used in selected soil borings at Study Area D to investigate the possible existence of fractures in the bedrock. An acoustic televiewer log was used because of its capability to provide an image similar to that of a video camera, and to provide azimuth and dip information for fractures and bedding structures. An optical televiewer was also used on several borings. The acoustic televiewer log is an oriented, high-resolution image of the borehole. This image is created using high-frequency acoustic sound waves. The data from this tool, used in conjunction with other geophysical tools described below, provided the location and orientation information for features such as fractures and lithologic contacts. Because the acoustic televiewer tool must be run in a water-filled boring to be effective, water was introduced into the boreholes prior to logging.

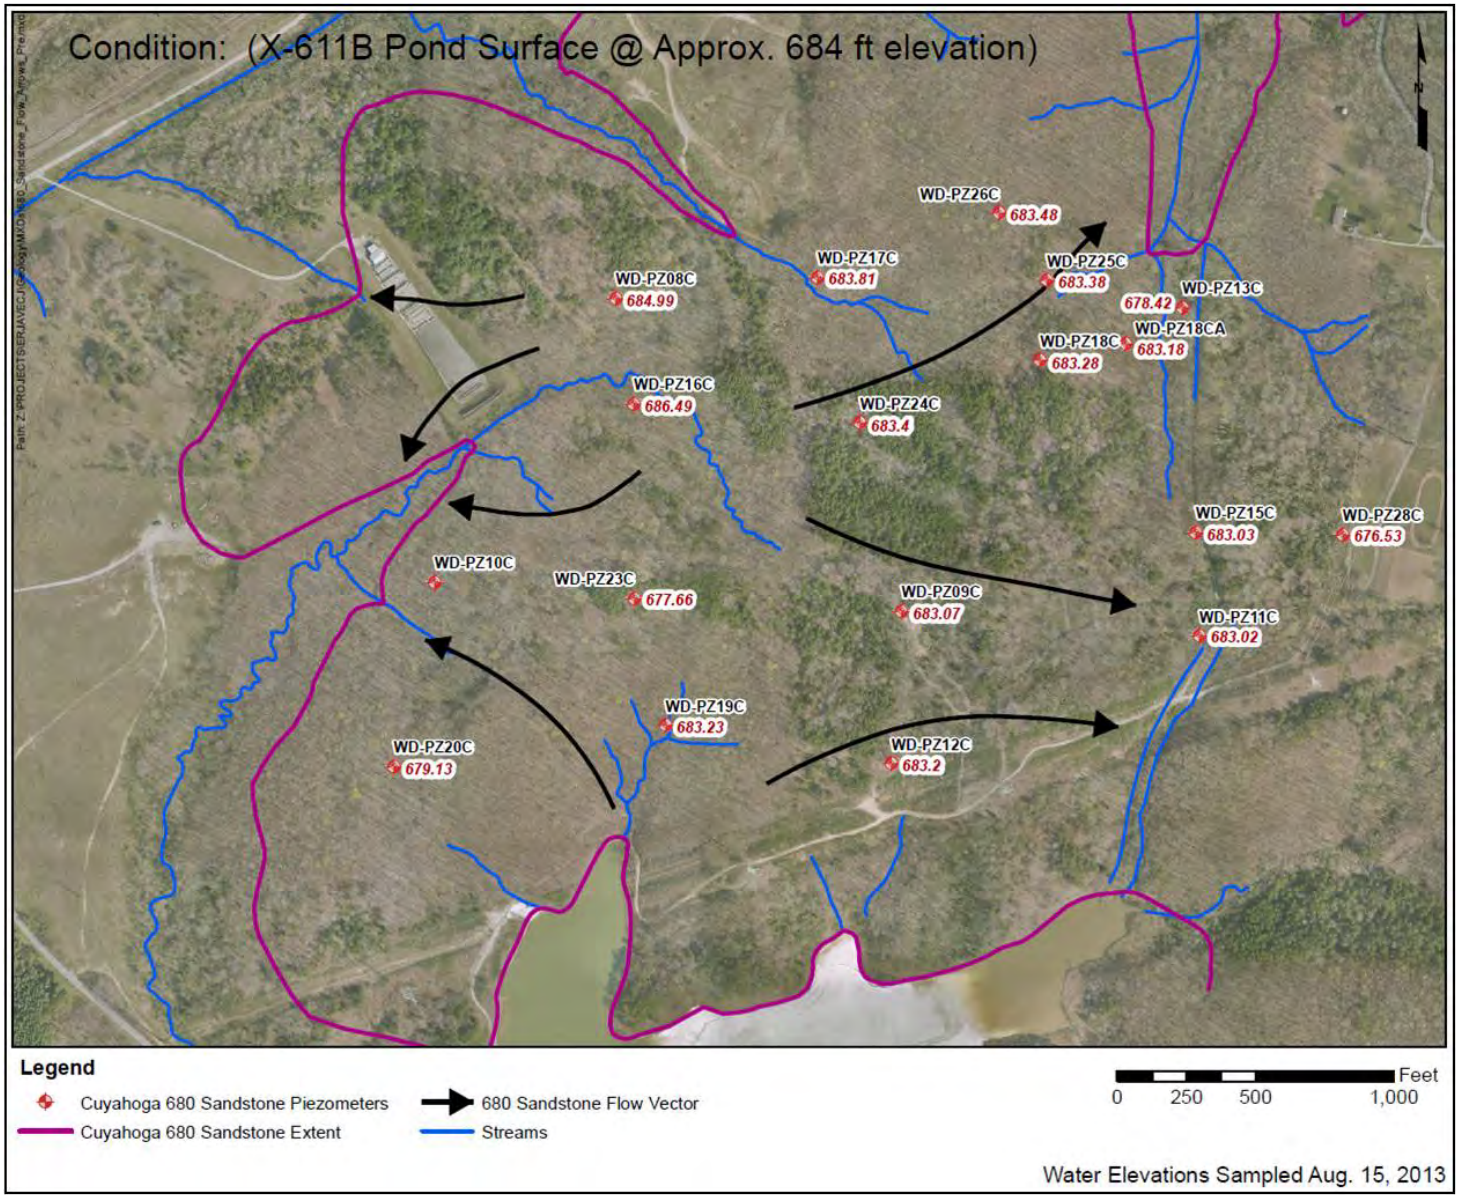

Figure 2.19. Groundwater Flow in the 680-ft Sandstone Under Current Conditions

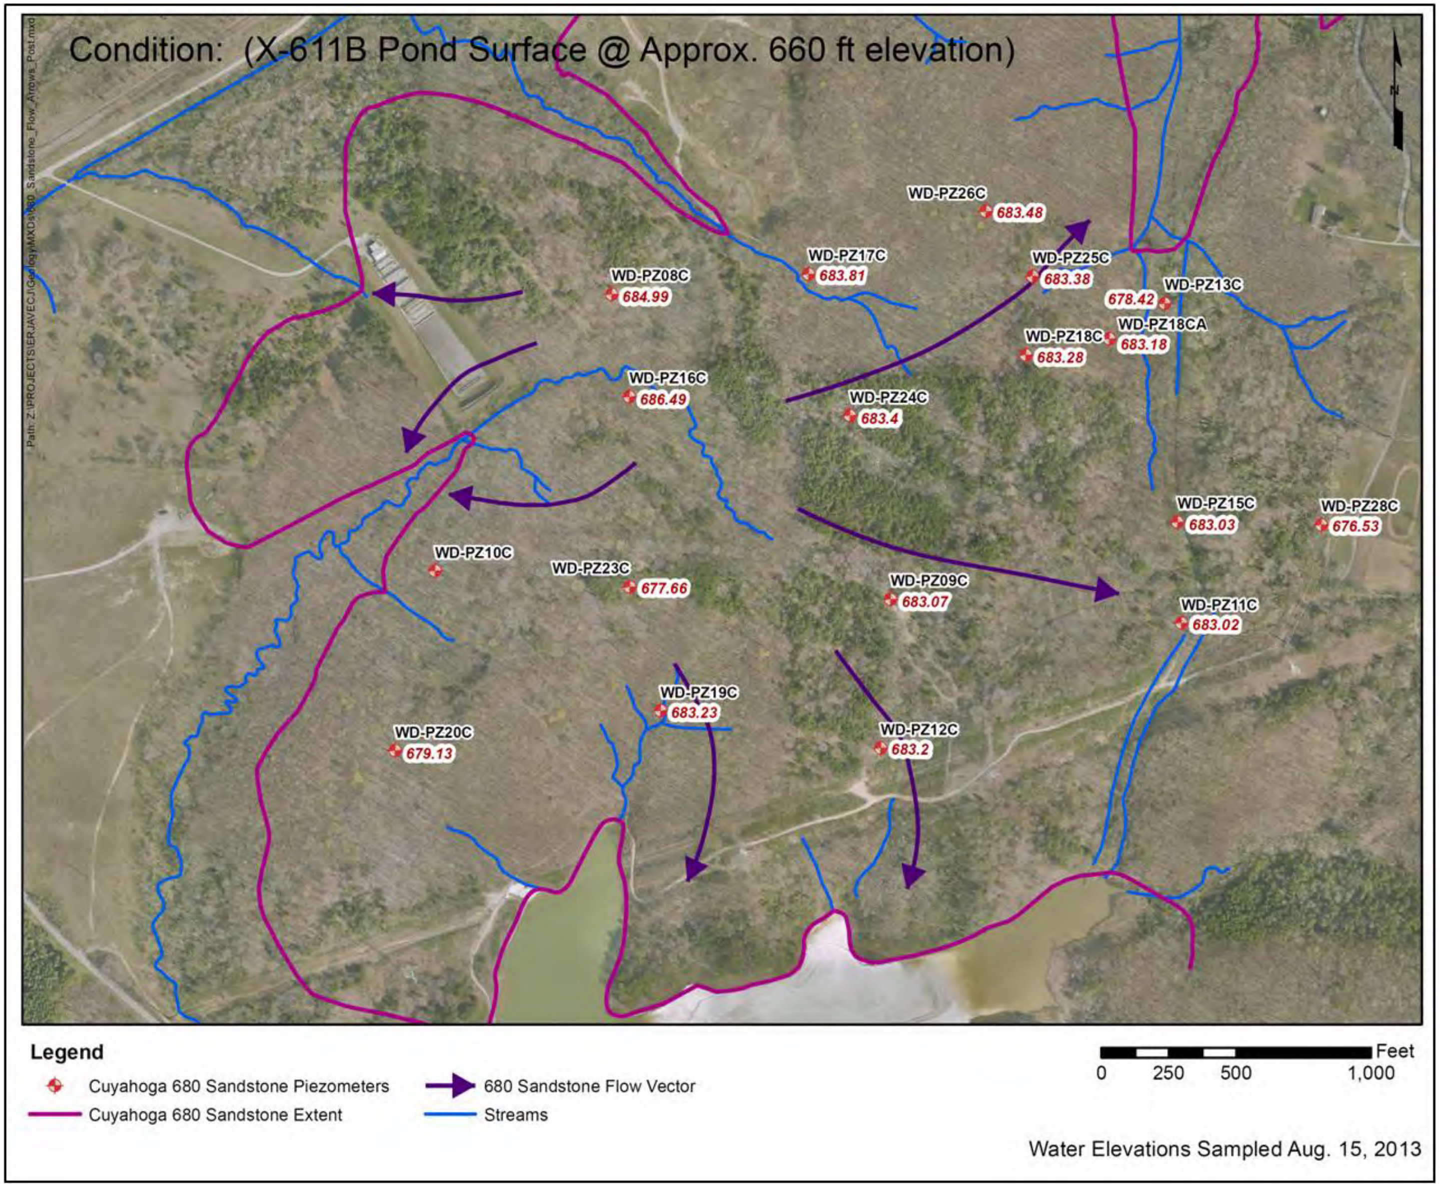

Figure 2.20. Groundwater Flow in the 680-ft Sandstone Under Future Conditions

A suite of geophysical logs was collected in each piezometer in Study Area D, including caliper, natural gamma, single-point resistance, normal and lateral resistivity, and the digital acoustic televiewer. Variations in the resistance, resistivity, and natural gamma logs, in conjunction with the caliper and acoustic televiewer log responses, allow the identification of lithologic changes and geologic features in the bedrock. Bedding plane fractures were noted at the top of the 680-ft sandstone in WD-PZ08C and WD-PZ13C, and a vertical fracture in the 680-ft sandstone was observed in WD-PZ09C and WD-PZ12C. The fractures in the 680-ft sandstone did not appear to extend into the shale above or below the sandstone. Other fractures, mostly bedding plane partings, were noted within the weathered bedrock zone (particularly in WD-SB-40). When WD-SB-40 was filled with water for the acoustic televiewer logging, the bedding plane fractures in the weathered zone (upper 26 ft) appeared to allow the water to drain relatively quickly. As discussed above, WD-SB-40 appears to be located in an area where the 720-ft sandstone lens zone is locally saturated. The geophysical logging reports are provided as attachments in Appendix B.

Groundwater Chemistry

The objective of groundwater sampling for this project was to characterize the general groundwater chemistry and determine the presence of any contaminants at the four study areas. Approximately 15 existing monitoring wells are currently sampled around Study Area B, and they provide sufficient characterization for that area. Results from those wells are reported in an annual groundwater report. The discussion that follows pertains to the newly installed piezometers and monitoring wells at Study Areas A, C, and D. These piezometers and monitoring wells are sampled quarterly. Following the waste disposition ROD, the piezometers and monitoring wells will be placed into the PORTS integrated groundwater monitoring program and evaluated for long-term monitoring or be plugged and abandoned as determined necessary.

Prior to sampling, the piezometers and monitoring wells are purged to remove any water that is not representative of the groundwater. Purging of the wells is accomplished using bladder pumps, impeller pumps, or bailers, depending on the yield of the well. The purge water is containerized and treated in an existing groundwater treatment facility.

Samples for VOC analysis are collected in such a way that no headspace exists in the sample containers, which minimizes the possible loss of organic compounds through volatilization. Groundwater samples that are to be analyzed for dissolved metals or total mobile metals are filtered to remove any residual particulate material that could alter the preserved metals content in the sample. Unfiltered samples are also collected to provide the total metals results for the groundwater.

Because many chemical constituents and physicochemical parameters evaluated in the sampling and analysis program are not chemically stable, sample preservation is required. The most prevalent sample preservation methods used at PORTS are pH control and the maintenance of sample temperature at 4°C plus or minus 2°C. The pH of samples is reduced to less than 2 by the addition of acid to the sample containers or increased to a pH greater than 12 by adding a base. (Filtered samples are filtered in the field prior to acidification.) Samples are preserved as required by the analytical laboratory and the analytical method specified in the Geotechnical SAP. QA/QC samples, including trip blanks, equipment rinsates, field blanks, and field duplicates, are collected during groundwater sampling activities.

Table 2.7 provides the major ion geochemistry of the groundwater in the piezometers and monitoring wells installed in Study Areas A, C, and D. Figure 2.21 shows the major ions plotted on a trilinear diagram. The three Gallia sand piezometers plot in a close grouping, with sulfate being the dominant anion (comprising 70 to 80 percent of the anions). There is no dominant cation in the groundwater in these Gallia piezometers but calcium and magnesium combined make up more than 80 percent of the cations. Five of the seven Berea monitoring wells have different hydrochemical signatures. All the Berea monitoring wells, with the exception of WD-MW05B and WD-MW07B, have a sodium chloride-type water that may indicate influence from natural brines similar to those associated with hydrocarbon reservoirs. WD-MW05B indicates no dominant cations or anions. WD-MW05B is located near the area where the Berea is recharged and the groundwater in that area may reflect a mixture of Gallia and Berea groundwater. WD-MW07B shows a signature intermediate between WD-MW05B and the remaining Berea monitoring wells. Figure 2.22 provides Stiff diagrams of the Berea monitoring wells in Study Area D and reflects the lower concentrations of sodium and chloride in WD-MW05B and WD-MW07B.

Table 2.7. Major Ion Geochemistry of Groundwater in Study Areas A, C, and D at PORTS

Piezometer/ Monitoring Well ID	Study Area	Zone Monitored	Cations (meq/L)			Anions (meq/L)

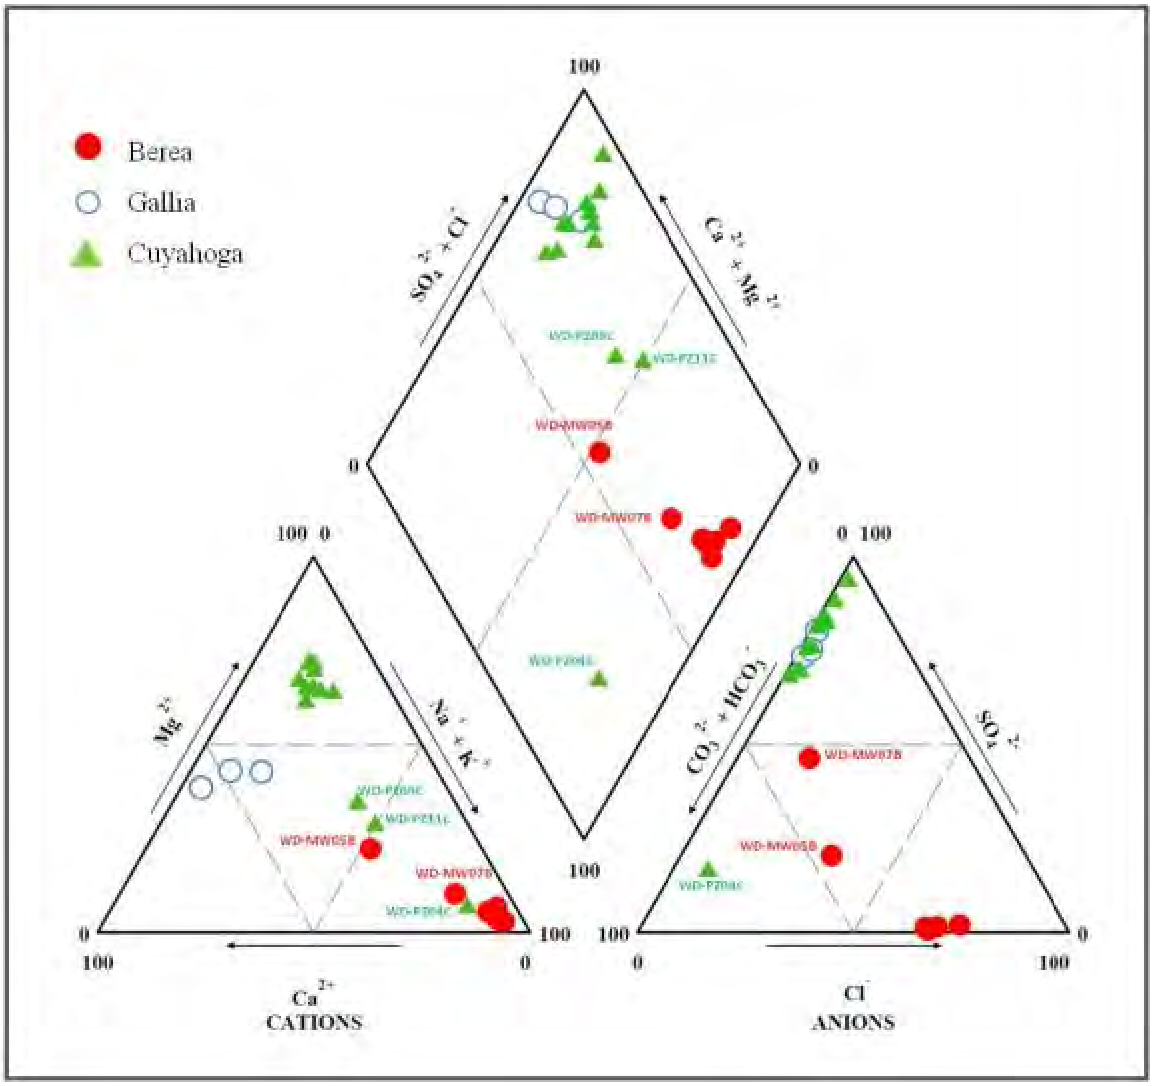

Figure 2.21. Major Ion Composition of Groundwater in Study Areas A, C, and D at PORTS

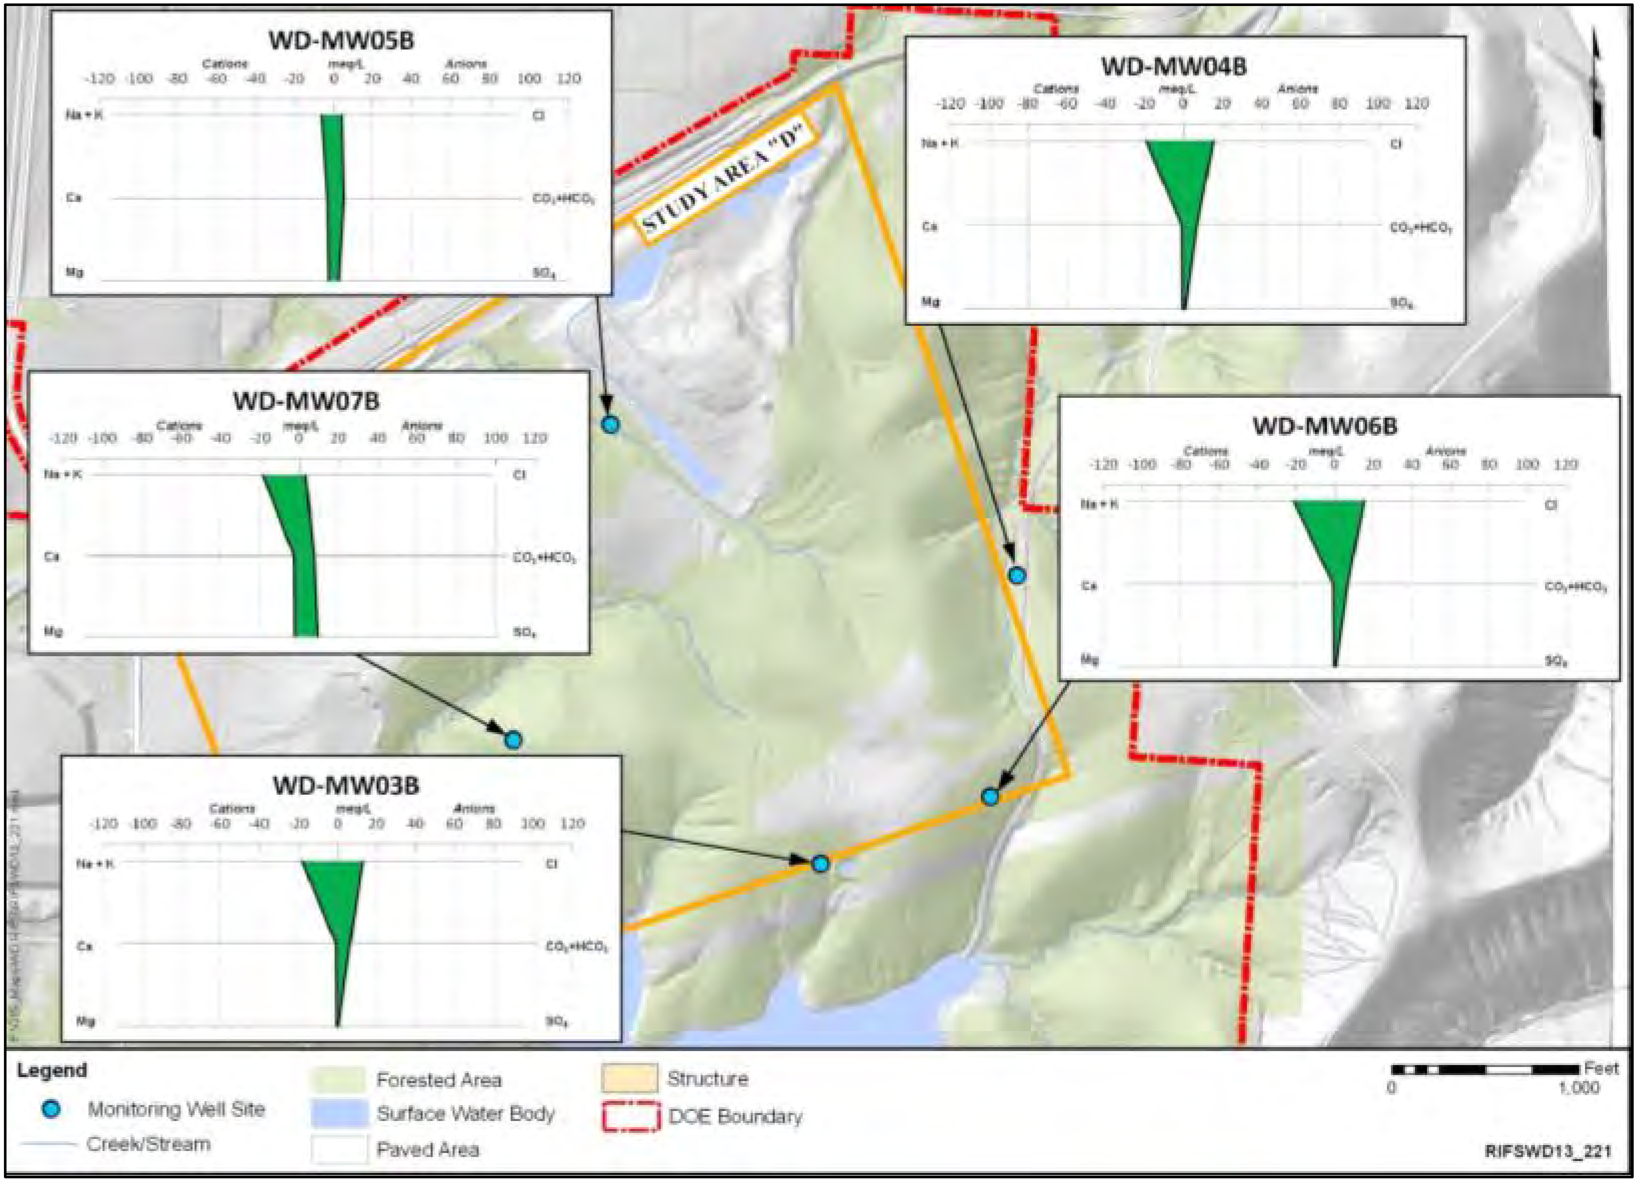

Figure 2.22. Stiff Diagrams for Berea Monitoring Wells in Study Area D

Twelve of the Cuyahoga piezometers, all located at Study Area D, have sulfate as the dominant anion. WD-PZ04C, located at Study Area C, has bicarbonate as the dominant anion. The cation composition in the Cuyahoga groundwater was variable with no consistently dominant cations (magnesium was more prevalent in ten of the Cuyahoga piezometers at Study Area D). Two Cuyahoga piezometers at Study Area D, WD-PZ09C and WD-PZ11C, display a different cation signature with magnesium comprising less than 35 percent of the cations. Magnesium in the remaining Cuyahoga piezometers at Study Area D is typically greater than 65 percent. Figures 2.23 and 2.24 show Stiff diagrams for the Cuyahoga piezometers at Study Area D. The different "pattern" for the Stiff diagrams in WD-PZ09C and WD-PZ11C, resulting from lower magnesium and sulfate, is evident on the trilinear diagram (Figure 2.21).

Total dissolved solids in the Cuyahoga piezometers at Study Area D ranged from approximately 1,530 to 10,800 mg/L with an average of 4,625 mg/L. The total dissolved solids, calculated by summing the individual major ions (calcium, magnesium, potassium, sodium, bicarbonate, carbonate, chloride, and sulfate) are provided in Appendix A, Table A.7. Sulfate is the dominant constituent in the Cuyahoga groundwater, comprising from 45 to 70 percent of the total dissolved solids. The total dissolved solids in the Cuyahoga Formation at Study Area C (WD-PZ04C) averaged 680 mg/L. Total dissolved solids in the Berea monitoring wells, excluding WD-MW05B and WD-MW07B, ranged from 1,100 mg/L to 1,700 mg/L with chloride comprising approximately 35 percent of the total dissolved solids. The drinking water standard (secondary maximum contaminant level [MCL]) for total dissolved solids and sulfate is 500 mg/L and 250 mg/L, respectively.

Groundwater results from the Gallia piezometers and Berea monitoring wells were compared to risk-based PRGs provided in the annual groundwater report (DOE 2011b). Only cobalt and copper in WD-PZ01G and WD-PZ02G exceeded the Gallia groundwater PRGs. Cobalt, which has a Gallia PRG of 0.013 mg/L, was detected at concentrations of 0.013 mg/L and 0.014 mg/L in WD-PZ01G and WD-PZ02G, respectively. Copper, with a Gallia PRG of 0.021 mg/L, was detected at concentrations of 0.023 mg/L and 0.026 mg/L in WD-PZ01G and WD-PZ02G, respectively. There were no detections of common PORTS contaminants such as TCE or technetium-99, with the exception of an estimated technetium-99 result of 1.82 pCi/L in WD-PZ02G.

Low concentrations of VOCs commonly associated with natural gas and petroleum (benzene, ethylbenzene, xylenes and/or toluene) were detected in all Berea monitoring wells at concentrations below risk-based PRGs. These compounds are routinely detected in Berea monitoring wells at PORTS as the Berea sandstone is a known oil- and gas-producing formation in Ohio with gas-production wells as close as eastern Pike County (DOE 1996e).

Conceptual Model for Groundwater Flow at PORTS

The groundwater flow system of the Minford and Gallia, as well as the Berea flow system, are well understood and documented in previous PORTS reports. The following discussion is specific to the upland areas around PORTS that are underlain by the Cuyahoga Formation.

The groundwater system in the upland areas around PORTS has two primary components: the shallow, weathered regolith and the deeper, unweathered bedrock. Groundwater occupies pore spaces in the shallow, weathered regolith. Because the bedrock has little primary porosity or permeability, groundwater occupies secondary porosity comprised of fractures/joints and bedding planes. The regolith, while thin, represents a temporary storage reservoir and is a source of recharge to the bedrock via fractures. In most areas, a transition zone between the regolith and bedrock, consisting of weathered bedrock, is present.

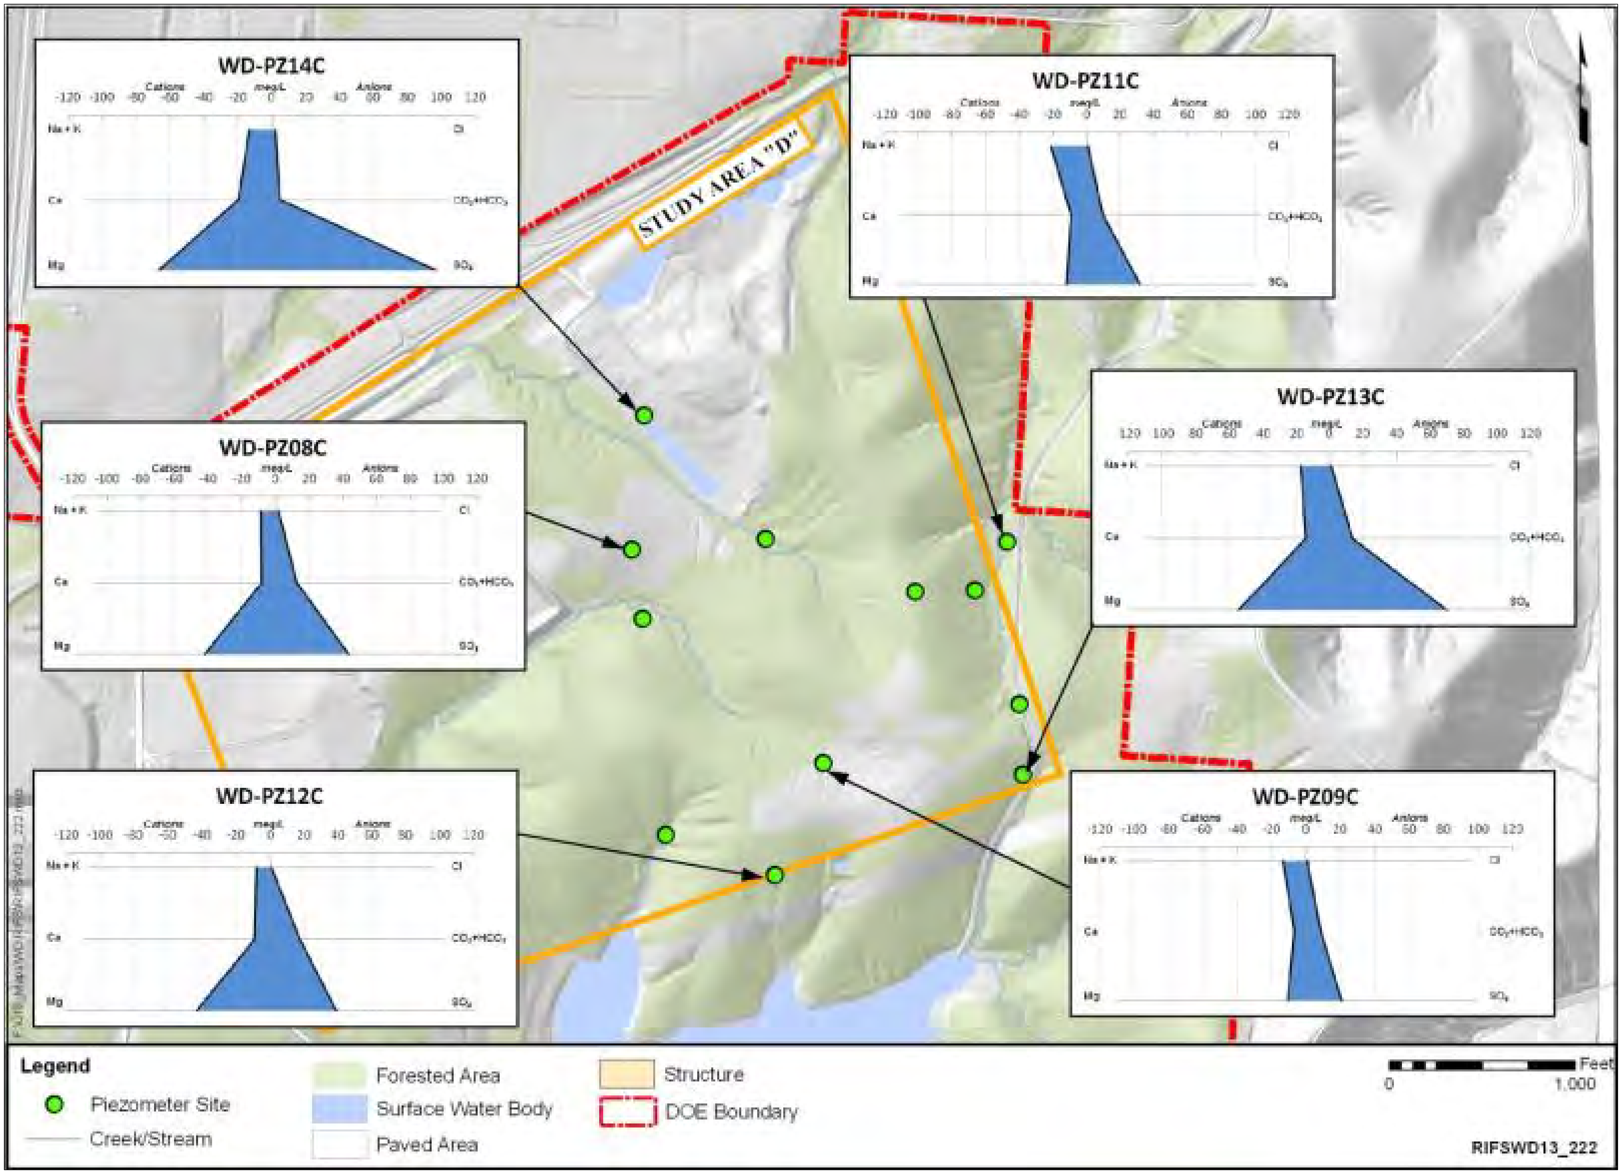

Figure 2.23. Stiff Diagrams for Piezometers WD-PZ08C, WD-PZ09C, WD-PZ11C, WD-PZ12C, WD-PZ13C, and WD-PZ14C

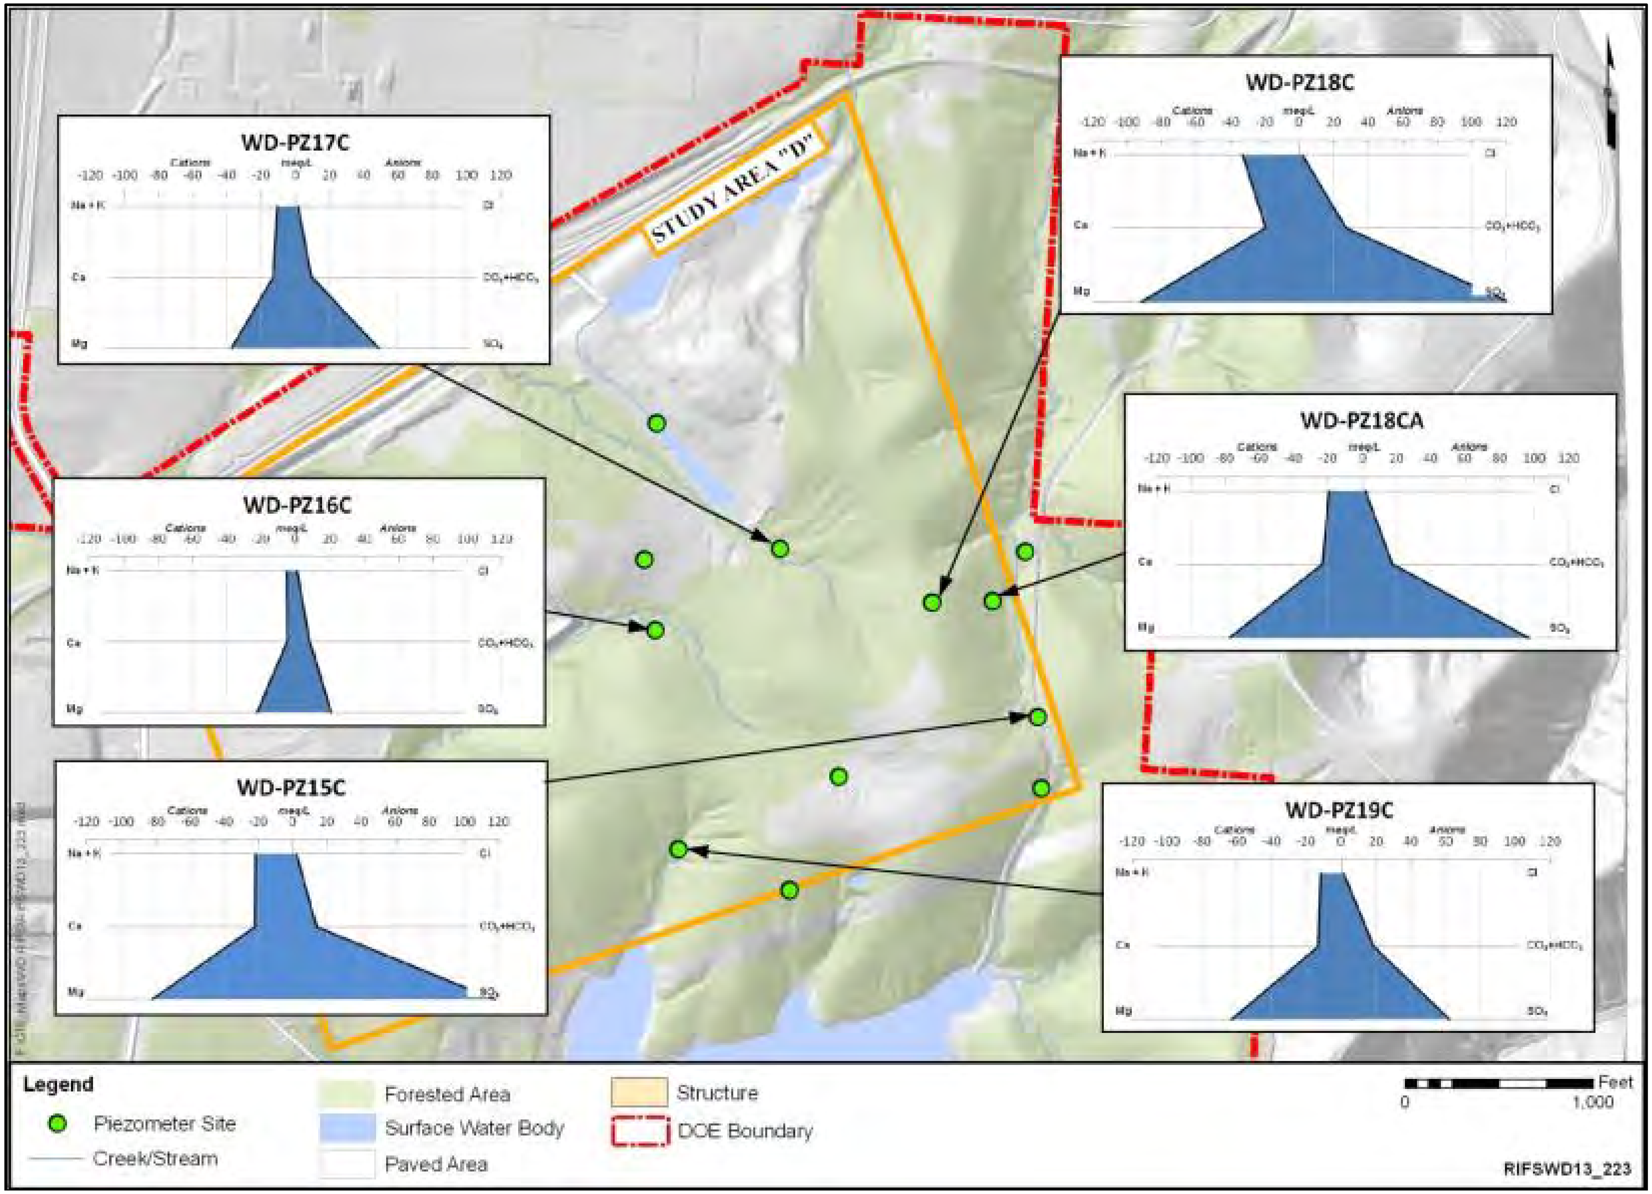

Figure 2.24. Stiff Diagrams for Piezometers WD-PZ15C, WD-PZ16C, WD-PZ17C, WD-PZ18C, WD-PZ18CA, and WD-PZ19C

The regolith is the shallow component of the upland groundwater system. The term “regolith,” as used in this report, includes all unconsolidated or poorly consolidated materials overlying bedrock in the upland areas from the top of competent bedrock upwards to the ground surface. Thus, the regolith includes soil, residuum, and colluvium. The regolith ranges from 2 ft to 20 ft thick and averages approximately 8 to 10 ft in borings at Study Areas C and D. The regolith generally is described as in-place weathered material lacking geologic structure. At PORTS, the regolith is typically light yellowish-brown to light gray clay and silt.

Partially weathered bedrock, likely fractured (due to stress-relief fracturing), characterizes the transition zone between the regolith and bedrock. Vertical fractures may be more common than observed in the cores or in borehole geophysical surveys. This zone is weathered, but not to the degree necessary to create substantial clay minerals. The weathering results in the bedrock within this zone having a color varying from yellowish-brown to light gray in contrast to the dark gray of the deeper, unweathered bedrock. The cores from the partially weathered bedrock of the transition zone retain most of the original geologic texture of the bedrock. The thickness of the weathered bedrock zone averages approximately 15 ft. The depth of weathering (regolith plus weathered bedrock) averages 20 to 25 ft.

A conceptual model of groundwater flow in the upland areas around PORTS assumes that water flows from high topographic areas to low topographic areas, particularly within the regolith. The movement of water in the regolith is characterized as interflow and/or throughflow (i.e., subsurface stormflow). Interflow is the lateral movement of water in the soil zone, where a more permeable geologic unit, such as the regolith, overlays a less permeable geologic unit. Interflow usually occurs following precipitation events. The infiltrated water moves laterally and then discharges on hillsides as ephemeral seeps (throughflow returning as wet weather conveyances) or directly into streams. (Throughflow is a subcomponent of interflow that returns to the surface, as overland flow, prior to entering a stream). While the influence of the water in the regolith on the local groundwater system was not directly determined, this conceptual model of interflow is supported by observation and understanding from other similar systems (note that if a disposal cell is constructed, this zone would be removed for installation of the bottom liner directly on top of competent bedrock). At Study Area C, the shallow water table in the regolith/weathered bedrock was approximately 14 ft below surface based on a historical dug well in that area. On hillsides and other areas where regolith is thin, it likely becomes unsaturated in late summer and early fall. Figure 2.25 presents a generic conceptual model for groundwater flow in the upland areas around PORTS (areas underlain by the Cuyahoga Formation).

In areas where fractures occur, or the bedrock (or weathered bedrock) is sandy and more permeable, some of the groundwater moves downward from the regolith to provide recharge to the deeper bedrock system (in test pits the more brittle sandstone layers were observed to have vertical fractures which did not extend into the overlying or underlying shale). Static surface water features, such as the X-611B Sludge Lagoon, may also provide recharge through contact with more permeable zones in the bedrock that outcrop below the water surface.

In the upland areas of PORTS, the Cuyahoga Formation contains several zones of thin sandstone layers. The upper sandstone zone is referred to as the 720-ft sandstone lens zone. The thickness of the individual sandstone lenses in the 720-ft sandstone lens zone average approximately 0.5 ft. While this “zone” is fairly continuous across Study Area D, the individual sandstone lenses that comprise this zone are difficult to correlate from boring to boring and do not appear to be continuous across Study Area D.

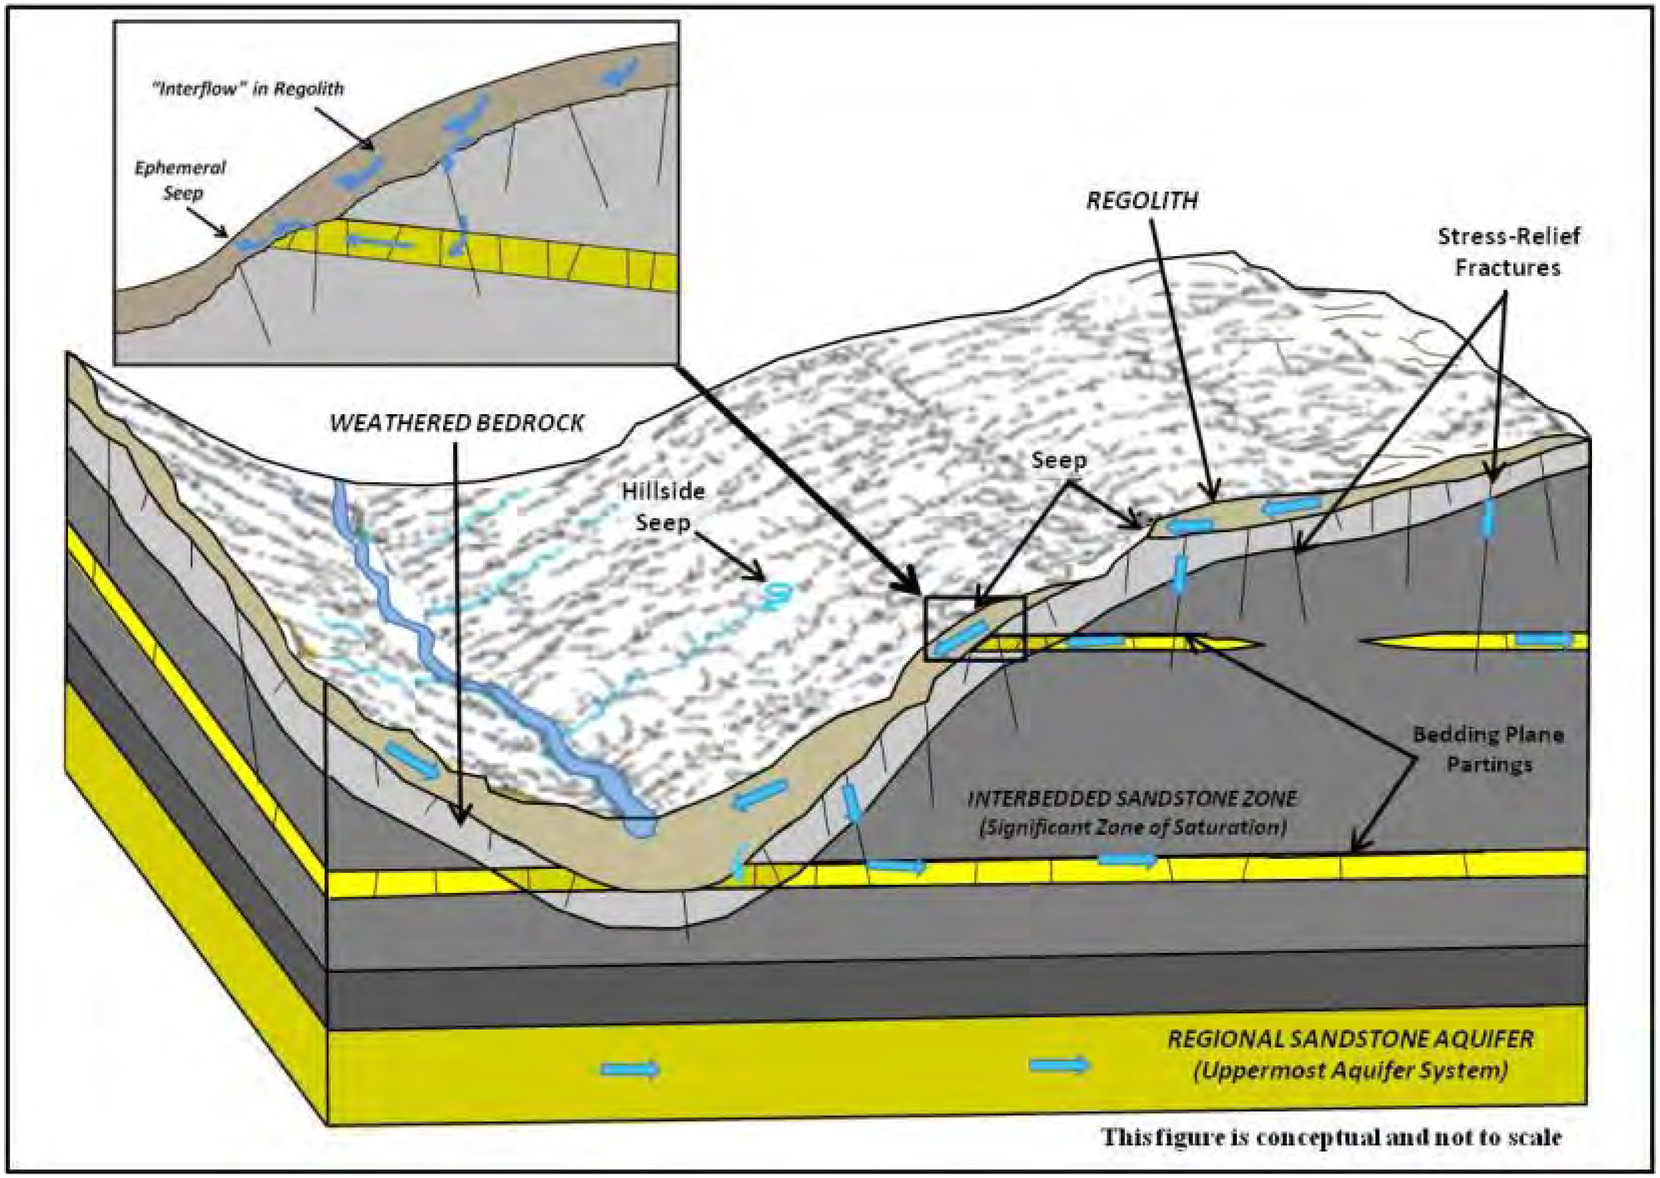

Figure 2.25. Generic Hillside Hydrogeologic Model for Upland Areas at PORTS

There is a localized area of saturation associated with the 720-ft sandstone lenses in the vicinity of WD-SB-40 and WD-PZ15C. The sandstone lenses receive recharge where they outcrop, or subcrop beneath the regolith (within the stream valley that WD-PZ15C is located within) or where they are close to the surface in the fractured and weathered bedrock. None of the other open-hole piezometers had a groundwater elevation that coincided with the 720-ft sandstone zone.

The next recognizable zone in depth is the 680-ft sandstone zone. This zone is comprised of an upper 2-ft-thick layer and a lower 0.4-ft-thick sandstone separated by approximately 2 ft of shale. Unlike the 720-ft sandstone zone, the individual sandstone layers in the 680-ft sandstone zone are continuous across Study Area D, except where removed by erosion to the west and north, and probably extend outside of the study area to the northeast and east, although the extent is limited by topography with the layer being eroded in the deeper valleys. These sandstones were also noted in several borings at Study Area C, but they were thinner and often described as siltstones as the unit tends to become more fine-grained from north to south.

The vertical hydraulic conductivity of the 680-ft sandstone zone at Study Area D was determined in laboratory testing to be 0.0005 ft/day to 0.004 ft/day. The horizontal hydraulic conductivity is estimated to be approximately 10 times that value. Joint and bedding plane partings may increase the permeability values by one or two orders of magnitude when compared to the intergranular permeability values alone. The only fractures noted during geophysical logging of seven piezometers at Study Area D were bedding plane fractures at the top of the 680-ft sandstone in WD-PZ08C and WD-PZ13C, a vertical fracture in the 680-ft sandstone in WD-PZ09C and WD-PZ12C, and bedding plane partings in the weathered bedrock. With the exception of the above mentioned fractures associated with the 680-ft sandstone, no fractures were observed in unweathered bedrock. The shale in the Cuyahoga Formation had vertical hydraulic conductivities much lower than the sandstone (range from 0.000001 to 0.0009 ft/day), based on laboratory testing.

Throughout the study period, the depth to the potentiometric surface as measured in the piezometers and monitoring wells was relatively consistent. At Study Area D, potentiometric levels are typically highest in WD-PZ16C. This piezometer is located in an area where the 680-ft sandstone subcrops beneath the regolith in a stream valley and receives recharge. Groundwater flow from this recharge area would tend to be radially outward but would be south-to-southeast beneath the proposed OSDC. Groundwater flow to the northwest from this recharge area may be limited as the dip of the sandstone is generally to the east-southeast.

The vertical gradient between the 680-ft sandstone zone and the Berea is estimated to be greater than 1ft/ft downward and in some areas is greater than 2 ft/ft due to the low permeability of the lower Cuyahoga Formation and the Sunbury shale. Hydraulic testing demonstrated a lack of communication between the Berea and the overlying saturated zones which suggests the fractures/joints do not extend to the Berea (stress-relief fracturing decreases with depth).

The groundwater chemistry of the Berea is significantly different from the overlying zone of saturation in the Cuyahoga. The Berea has a sodium chloride-type hydrochemical facies while the Cuyahoga has a magnesium sulfate-type hydrochemical facies. The high concentrations of sulfate in the Cuyahoga are probably related to the oxidation of sulfide minerals in the shale. The exception is WD-PZ09C and WD-PZ11C which demonstrate a sodium-magnesium sulfate-type water chemistry. The sodium concentration of these two piezometers, in milliequivalents per liter, accounts for 45 percent of the total cations whereas sodium only comprises 15 percent of total cations in the remaining Study Area D piezometers. This seems to reflect more cation exchange of magnesium for sodium on the surface of clay particles in the shale. The lowest total dissolved solids in the Cuyahoga occur in WD-PZ09C and WD-PZ16C. WD-PZ16C is located near a recharge area where the 680-ft sandstone subcrops beneath the regolith and WD-PZ09C appears to be located in a more permeable zone potentially connected to recharge areas.

Yield was tested in 12 Cuyahoga piezometers at Study Area D. Only two could sustain a yield greater than 0.1 gpm. The yield in the remaining piezometers ranged from 0.0007 gpm to 0.05 gpm. The average of all Cuyahoga piezometer yields was 0.16 gpm with a median yield of 0.002 gpm. The logarithmic mean, which may be more appropriate given the distribution, is less than 0.01 gpm. Yield testing in four Berea monitoring wells at Study Area D ranged from 0.008 gpm at WD-MW05B to 0.02 gpm at WD-MW06B with a logarithmic mean of 0.01 gpm.

The Berea sandstone, the regional aquifer, occurs at an average elevation of approximately 625 ft AMSL. The Berea is separated from the Cuyahoga Formation by approximately 20 ft of Sunbury shale. The upper 10 to 15 ft of the Berea, which has a total thickness of approximately 35 ft, consists of a massive sandstone bed. The hydraulic conductivity determined by single-well aquifer tests of the Berea sandstone ranges from 4.5×10^{-3} to 15.0 ft/day with a mean value of 0.16 ft/day. The higher hydraulic conductivity tends to occur in areas where the Sunbury shale is absent and the Berea has been weathered. The Berea typically has yields greater than 1 gpm and is often the target for installation of residential water supply wells in this area. Yield measurements are available for three Berea wells (two residential wells and one PORTS monitoring well) within a 1-mile radius around Study Area D. The average yield based on those three wells is 1.0 gpm. The Berea represents the uppermost aquifer system at Study Areas C and D (in the upland areas where the Minford/Gallia is absent).

The sandstone zones in the Cuyahoga Formation, the “720-ft sandstone lens zone” and the “680-ft sandstone” are considered significant zones of saturation (a “significant zone of saturation,” as defined at *OAC* 3745-27-01, means a zone of saturation that may act as a preferential pathway of migration away from the limits of solid waste placement). These sandstones can transmit groundwater more readily than the overlying or underlying shale but they are thin (2 ft thick or less) and have a low hydraulic conductivity and a low yield. Only two piezometers demonstrated a yield greater than 0.1 gpm and testing indicated little to no hydraulic connection to nearby piezometers and borings. The water quality of the Cuyahoga is undesirable with sulfate concentrations ranging from 660 mg/L to 6,600 mg/L (the secondary MCL for sulfate is set at 250 mg/L).

2.2.2.2 Subsurface soil investigation

For investigation of subsurface soil, several intrusive field methods were used to obtain the required geotechnical, geochemical, and analytical data, as outlined in the Geotechnical SAP. These methods included CPT and drilling in both unconsolidated and bedrock formations to collect soil samples for geotechnical, geochemical, and analytical testing. CPT, an in situ method used to determine geotechnical properties of soils, was used to identify the geologic stratigraphy, determine depth to bedrock, and verify the depth to groundwater in unconsolidated materials.

The numbers and types of samples collected from each boring are provided in Table 2.8. Because less data were initially available for Study Areas A, C, and D, most of the sampling was performed in those areas. The types (and numbers) of geotechnical and hydraulic conductivity tests performed within each study area are listed in Table 2.9. Appendix C contains the geochemical and geotechnical sample results.

Table 2.8. Summary of Subsurface Soil Sampling Activities in Study Areas at PORTS

The planned numbers of analyses are in parentheses.

ASTM = American Society for Testing and Materials

CPT was used to collect geotechnical and geological data within the unconsolidated strata. This testing primarily determines the bearing capacity and pore water pressure of the unconsolidated soil. The CPT work followed ASTM D 3441, *Standard Test Method for Mechanical Cone Penetration Tests for Soil*. CPT was used at 21 locations in both unconsolidated subsurface soils and weathered bedrock until refusal was reached, and it provided a continuous readout of tip and sleeve resistivity and pore pressure to bottom depth. At Study Areas C and D, the CPT results supplemented the soil boring data in providing the depth to bedrock. The average depth to competent bedrock (based on auger refusal) at Study Area D was approximately 13 ft. The average depth of weathering at Study Area D, based primarily on color change in the rock core, was 22 ft.

Samples for geochemical, geotechnical, and contaminant analyses were collected with split-spoon samplers and/or Shelby tubes during the course of drilling. Sampling conformed to ASTM D 1586, *Standard Test Method for Standard Penetration Test (STP) and Split-Barrel Sampling of Soils* and ASTM D 1587, *Standard Practice for Thin-Walled Tube Sampling for Soils for Geotechnical Purposes*. Once competent bedrock was encountered, sampling conformed to ASTM D 2113, *Standard Practice for Rock Core Drilling and Sampling of Rock for Site Investigations*.

The locations of soil borings are shown in Figures 2.26 through 2.28. Seventy-one soil borings were advanced to bedrock or into bedrock at the four study areas. The borehole depths for the soil borings, provided in Table 2.7, ranged from approximately 53 to 100 ft below ground surface (bgs) at Study Area A, 42 to 70 ft bgs at Study Area B, 67 to 100 ft bgs at Study Area C, and 10 to 148 ft bgs at Study Area D.

Soil boring samples consisted of Shelby tube and split-spoon samples from discrete depth intervals. Geotechnical analyses (such as Atterberg limits, water content, consolidation, and unconfined compression), geochemical analyses (such as K_d, TOC, and cation exchange), and contaminant analyses were conducted on selected soil samples. Soil samples representing each geologic stratum were used for batch testing to determine site-specific K_d values for uranium isotopes and technetium-99.

Samples for geochemical analyses (K_d, TOC) were collected from selected borings at the depths of the various geologic strata. The TOC in soil and rock, used in fate and transport modeling of organic contaminants, was measured in 58 samples. The median value of the detections was 0.00495 kg/kg, or 0.495 percent organic carbon. The dataset had several values greater than 0.047 kg/kg which were primarily from the Sunbury shale. The Sunbury shale is characterized as an organic rich unit. One sample from the Berea sandstone at WD-SB-24 had a reported value of 0.071 kg/kg. (The drilling log for this boring noted a strong hydrocarbon odor from the Berea.) The median value of TOC results without the Sunbury and Berea results, which appear to be a separate sample population, is 0.0044 kg/kg. Figure 2.29 provides a comparison of the TOC results from the four study areas. The TOC is higher at Study Areas C and D where samples were collected from the regolith and shale bedrock compared to Study Areas A and B where samples were collected from the Minford and Gallia of the Teays Formation.

Because site-specific K_d values have already been determined for several metals, these analyses focused on developing site-specific K_d values for the radionuclides uranium and technetium-99 only. A total of 40 soil/rock samples representing various geologic strata were collected from specified soil borings and used for K_d analyses.

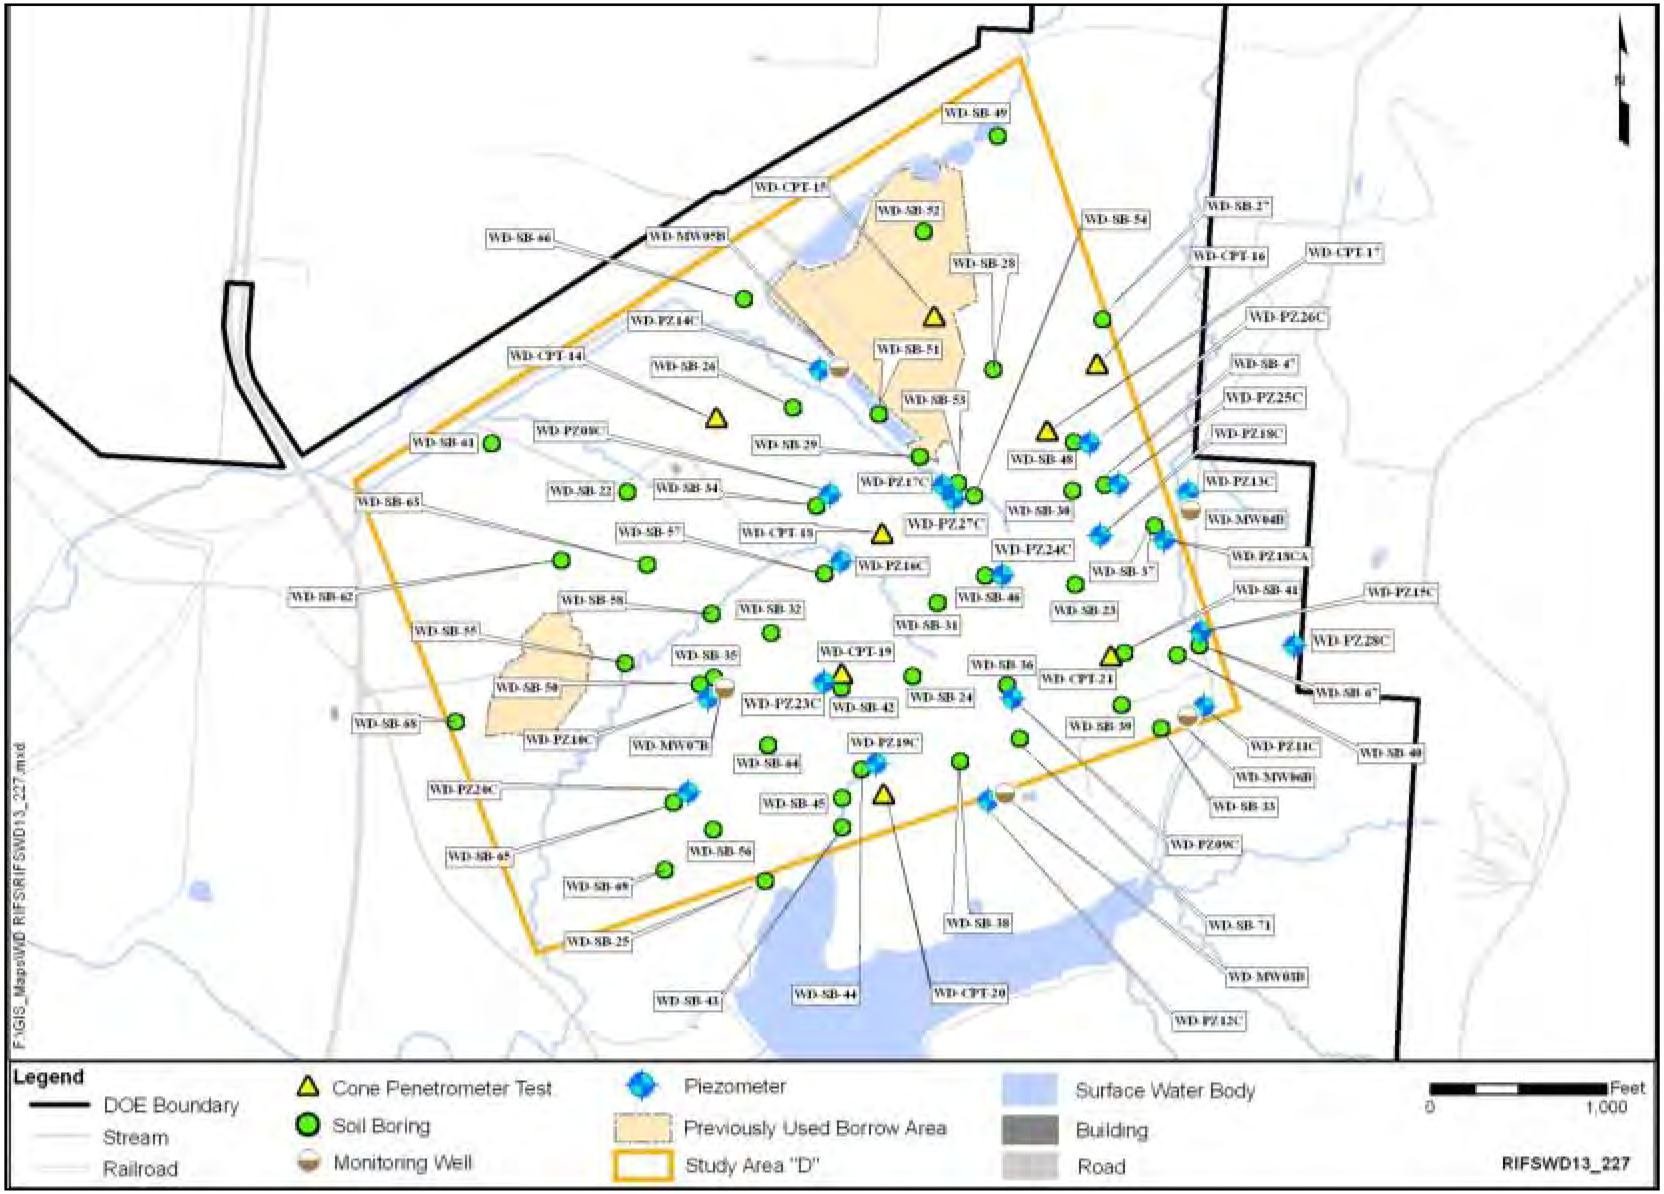

Figure 2.28. Boring Locations in Study Area D at PORTS

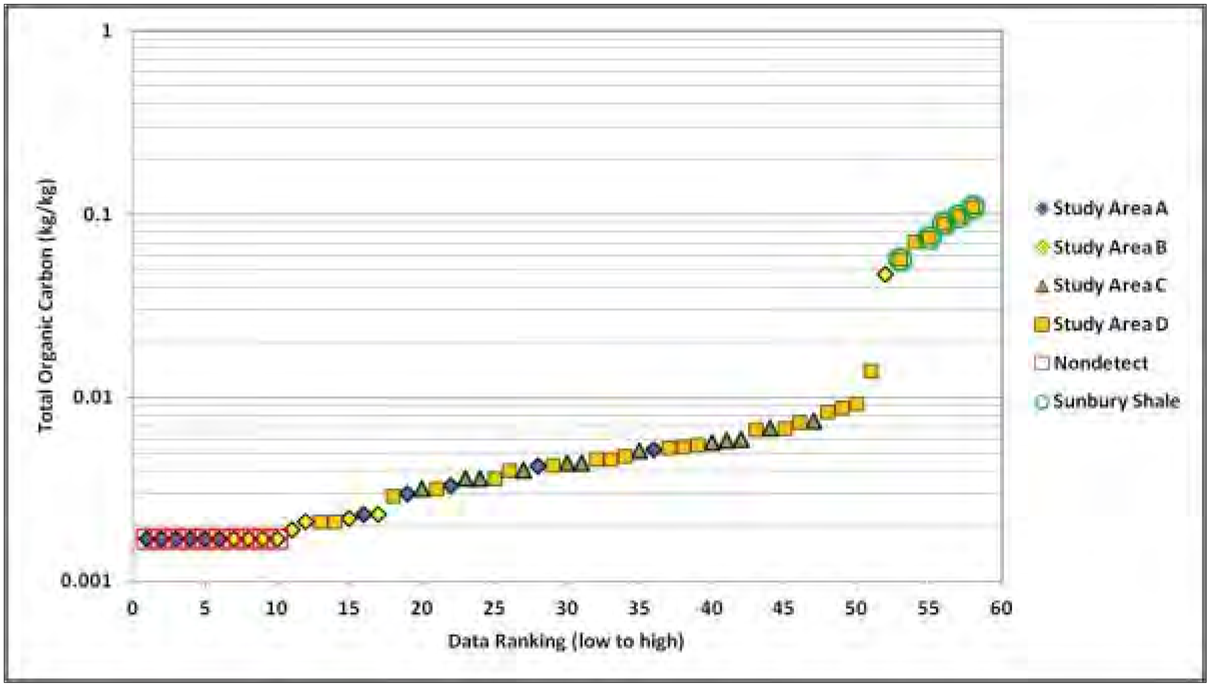

Figure 2.29. TOC Measurements for the RI/FS Study Areas at PORTS

The K_d analyses were performed to determine how species of uranium and technetium-99 in groundwater and soil partition between phases. This information is important in the analysis and evaluation of the retardation of uranium and technetium, and potential contaminant transport through the geologic strata. To obtain the most representative results, standard adsorption tests following ASTM C 1733 were performed on collected soil/rock samples, using both contaminated groundwater from the location and spiked water. The initial levels, or concentrations, of uranium and technetium-99 in the soil/rock samples and groundwater were determined by laboratory analyses. A summary of the results of the K_d analyses is listed in Table 2.10. The first batch of K_d results for uranium was highly uncertain because the uranium in the groundwater was at low activities. The results for the first batch of uranium K_d analyses were not considered to be representative and are not included in Table 2.10. The location groundwater was spiked with uranium for subsequent batch testing. Figure 2.30 shows the variation of K_d values with depth at WD-SB02 and WD-SB05. Distribution coefficients for waste were also determined with technetium ranging from 2.02 to 2.05 mL/g and uranium ranging from 246 to 634 mL/g. All K_d results and laboratory reports are provided in Appendix C.

Table 2.10. K_d Analytical Results for PORTS

Constituent	Geologic Unit	Min (mL/g)	Max (mL/g)	Median (mL/g)	Geometric Mean (mL/g)	Mean (mL/g)	Standard Error of the Mean (mL/g)	Number of Samples
Technetium-99	Minford	2.72	4.97	4.01	3.79	3.84	0.16	15
	Gallia	4.32	8.16	7.29	6.36	6.59	1.16	3

	Sunbury	757	757	NA	NA	NA	NA	1
	Berea	1.13	1.94	1.54	1.48	1.54	0.41	2

Max = maximum detected value
Min = minimum detected value
NA = not applicable

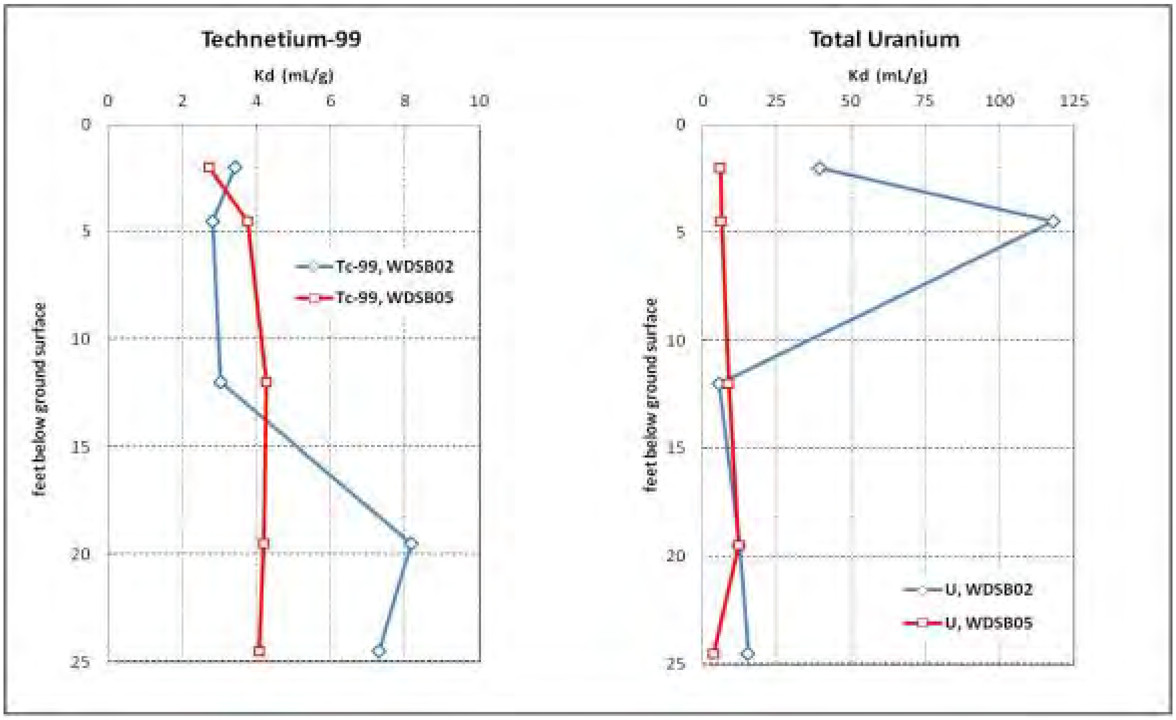

Figure 2.30. Variation of K_d for Technetium-99 and Total Uranium with Depth at PORTS

Soil/rock samples were collected for contaminant analysis as well as being evaluated for mineralogy. A report describing the mineralogy of four soil and six bedrock samples is provided in Appendix C. Soil/rock samples for VOC analysis were collected from near the base of the split-spoon sampler or core tubes soon after removal from the core barrel. Then the lithology of the sample was described and recorded. After the description of the lithology was completed, the soil was placed in a clean bowl and mixed to homogenize the sample, except in cases where the soil was stiff and could not be mixed. The resulting mixture was placed in the appropriate sample jars for analysis. In addition to contaminant characterization samples from the unconsolidated Minford, Gallia, or residual soil above the bedrock, samples were also collected from bedrock formations for chemical analysis. Samples for contaminant analysis were typically collected from the following depths, where not in conflict with a geotechnical or geochemical sample: 0 to 1 ft, 3 to 5 ft, 10 to 12 ft, 17.5 to 19.5 ft, and 22.5 to 24.5 ft.

Tables 2.11 through 2.14 provide a summary of the analytical results for soil at the four study areas. In addition to providing the minimum and maximum detected values for many of the analytes, they were also screened against Type 2 industrial screening levels found in the PORTS Risk Methods document (DOE 2011b). The Type 2 screening levels represent concentrations below which no significant human health threats are anticipated. The Type 2 industrial screening levels were calculated using standard EPA exposure equations and pathway models to account for the ingestion of and dermal contact with soil or dust, inhalation of particulates, and inhalation of volatiles (DOE 2013a).

Toluene	47	8.20×10^{-4}	3.80×10^{-3}	2/47	7.21×10^{3}	No
Total Xylene	47	4.70×10^{-3}	4.70×10^{-3}	1/47	348	No
Radionuclides	**Total Samples**	**Min Value (pCi/g)**	**Max Value (pCi/g)**	**Ratio Detect/Total**	**Type 2 Industrial Screening Level[a] (pCi/g)**	**Exceeds Screening Level?**
Plutonium-239/240	36	3.35×10^{-2}	4.50×10^{-2}	2/36	24.0	No
Uranium-233/234	58	0.569	1.37	58/58	56.5	No
Uranium-235	58	2.37×10^{-2}	7.82×10^{-2}	50/58	0.867	No
Uranium-238	58	0.546	1.38	58/58	3.66	No

[a] Type 2 industrial screening levels are from Table 2 in the PORTS human health Risk Methods document (DOE 2013a). Only constituents that were detected and have a Type 2 screening value provided in the Risk Methods document are listed in the table.

[b] The "Total Uranium" analyses cannot be directly compared to isotopic uranium results. "Total Uranium" was determined by Method 6020 with a sample preparation that only includes a partial dissolution (nitric acid only) to determine the environmentally available metals. The isotopic uranium samples were analyzed using alpha spectroscopy where the sample preparation included a more aggressive dissolution process. Because of the sample preparation process, the alpha spectroscopy analyses yield greater uranium values.

Table 2.12. Analytical Results Summary for Soil in Study Area B at PORTS (Continued)

Radionuclides	Total Samples	Min Value (pCi/g)	Max Value (pCi/g)	Ratio Detect/Total	Type 2 Industrial Screening Level[a] (pCi/g)	Exceeds Screening Level?
Uranium-233/234	20	0.519	7.22	20/20	56.5	No
Uranium-235	20	2.84×10^{-2}	0.285	16/20	0.867	No
Uranium-238	20	0.596	7.16	20/20	3.66	**Yes**

[a] Type 2 industrial screening levels are from Table 2 in the PORTS human health Risk Methods document (DOE 2013a). Only constituents that were detected and have a Type 2 screening value provided in the Risk Methods document are listed in the table.

[b] The "Total Uranium" analyses cannot be directly compared to isotopic uranium results. "Total Uranium" was determined by Method 6020 with a sample preparation that only includes a partial dissolution (nitric acid only) to determine the environmentally available metals. The isotopic uranium samples were analyzed using alpha spectroscopy where the sample preparation included a more aggressive dissolution process. Because of the sample preparation process, the alpha spectroscopy analyses yield greater uranium values.

Max = maximum detected value
Min = minimum detected value
PORTS = Portsmouth Gaseous Diffusion Plant

The only analytes exceeding the Type 2 screening levels were arsenic, chromium, cobalt, and uranium-238. Arsenic was analyzed for in 175 samples, and 169 of those had concentrations that exceeded the Type 2 screening level of 3.81 mg/kg. A previous background study for PORTS (DOE 1996e) indicated Minford soils having a background arsenic value of 31 mg/kg, which is greater than the Type 2 screening value for arsenic (3.81 mg/kg). A new study to determine soil background values for PORTS was initiated in 2012. The new study will evaluate soil background in other geologic units in addition to the Minford soils. Chromium exceeded the Type 2 screening level in 155 of 175 samples. The Type 2 screening level for chromium is based on chromium (VI), which is considered a more toxic form, although the analytical method did not differentiate between chromium (VI) and chromium (III). Cobalt exceeded the Type 2 screening level in 2 of 175 samples. Study Areas B, C, and D also exhibited Type 2 screening level exceedances for uranium-238 in 13 samples.

Analytical results for 111 samples from the Minford member, collected from 14 boring locations, were compared to previously determined Minford soil background values. Background values were exceeded in 68 of the samples. The constituents that exceeded background values included aluminum, arsenic, barium, calcium, cobalt, iron, lead, magnesium, manganese, mercury, nickel, sodium, gross alpha, and gross beta. Constituents not exceeding background include beryllium, cadmium, chromium, copper, selenium, silver, thallium, total uranium, vanadium, and zinc.

Several organic compounds were sporadically detected at all four study areas. These included six detections of TCE at Study Area B, two detections of PCBs at Study Area A, a single detection of cis-1,2-dichloroethene at Study Area C, and occasional detections of PAHs at Study Areas A, B, and C. Many of the detections were estimated with a "J" validation qualifier. Common laboratory contaminants (e.g., acetone, 2-butanone, methylene chloride, and phthalates) were detected in several samples from all four locations. Appendix A contains the analytical data from the samples collected at the four study areas. Figures 2.31 through 2.33 provide the locations and maximum concentrations of VOCs detected in soil at each study area.

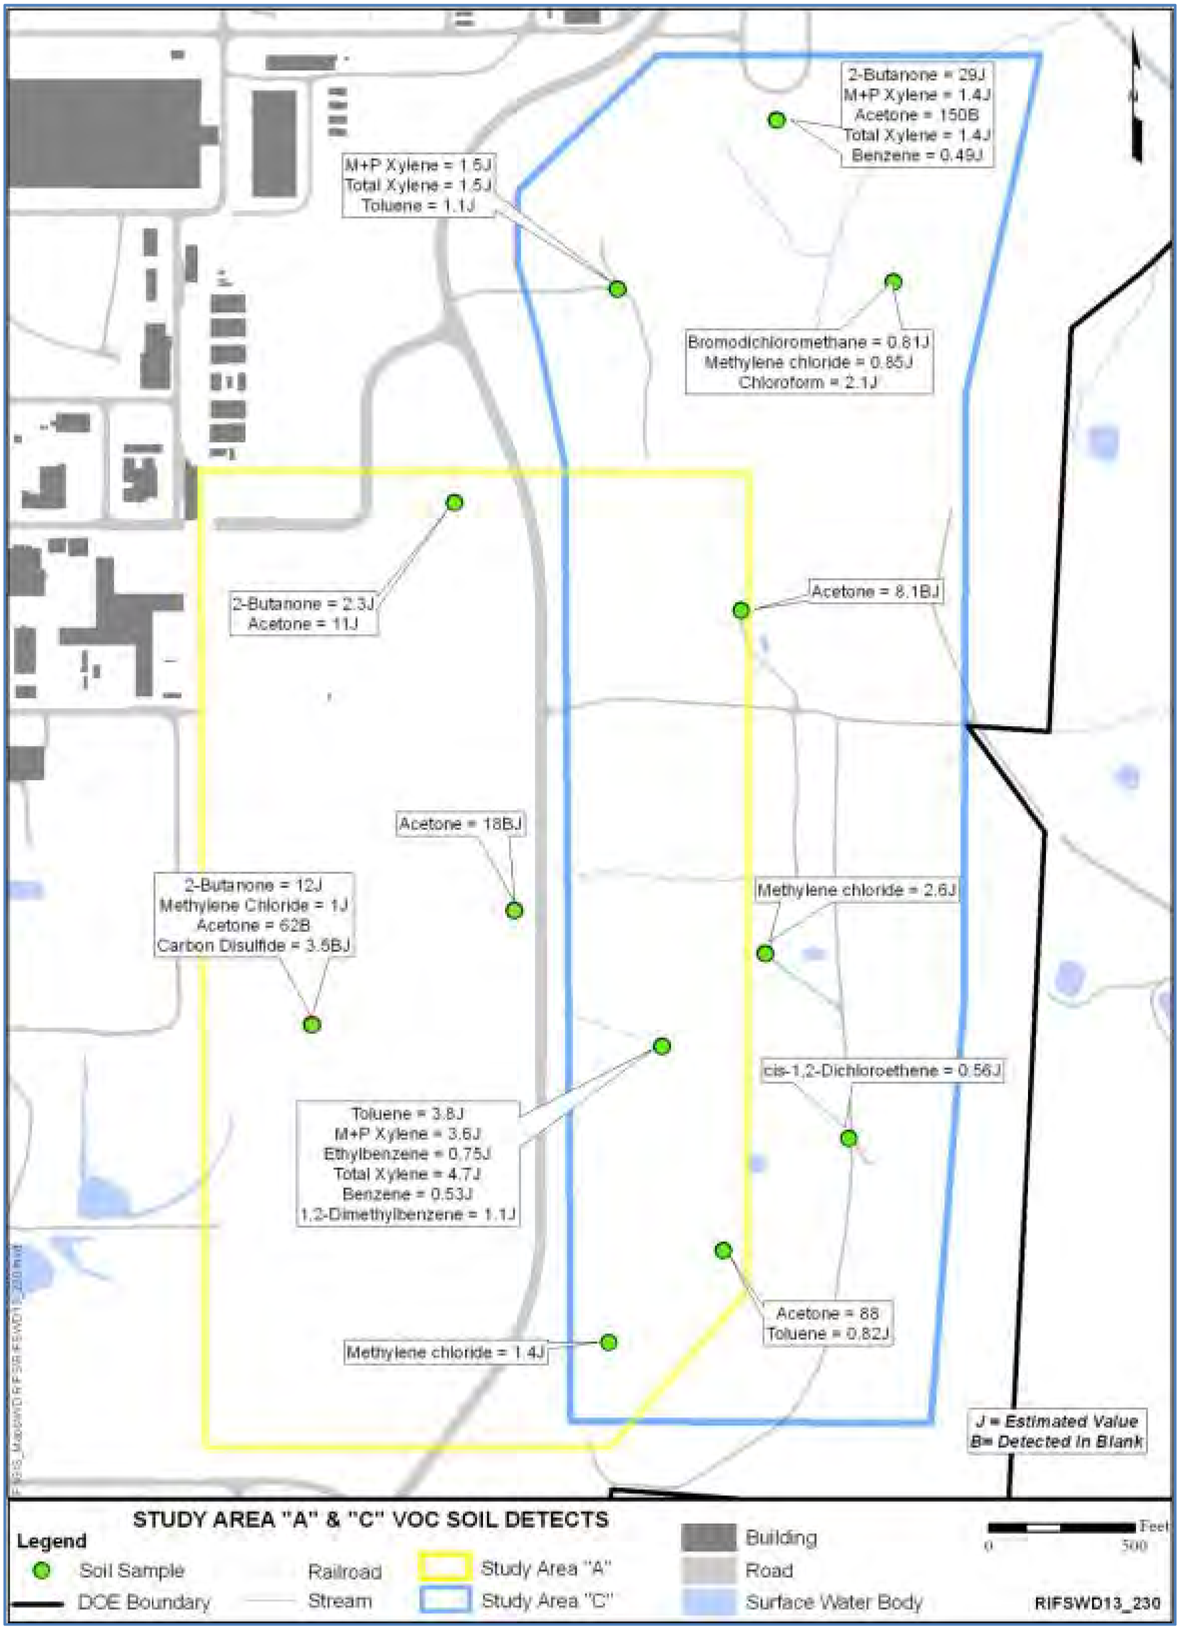

Figure 2.31. VOCs Detected in Soils at Study Area A and Study Area C

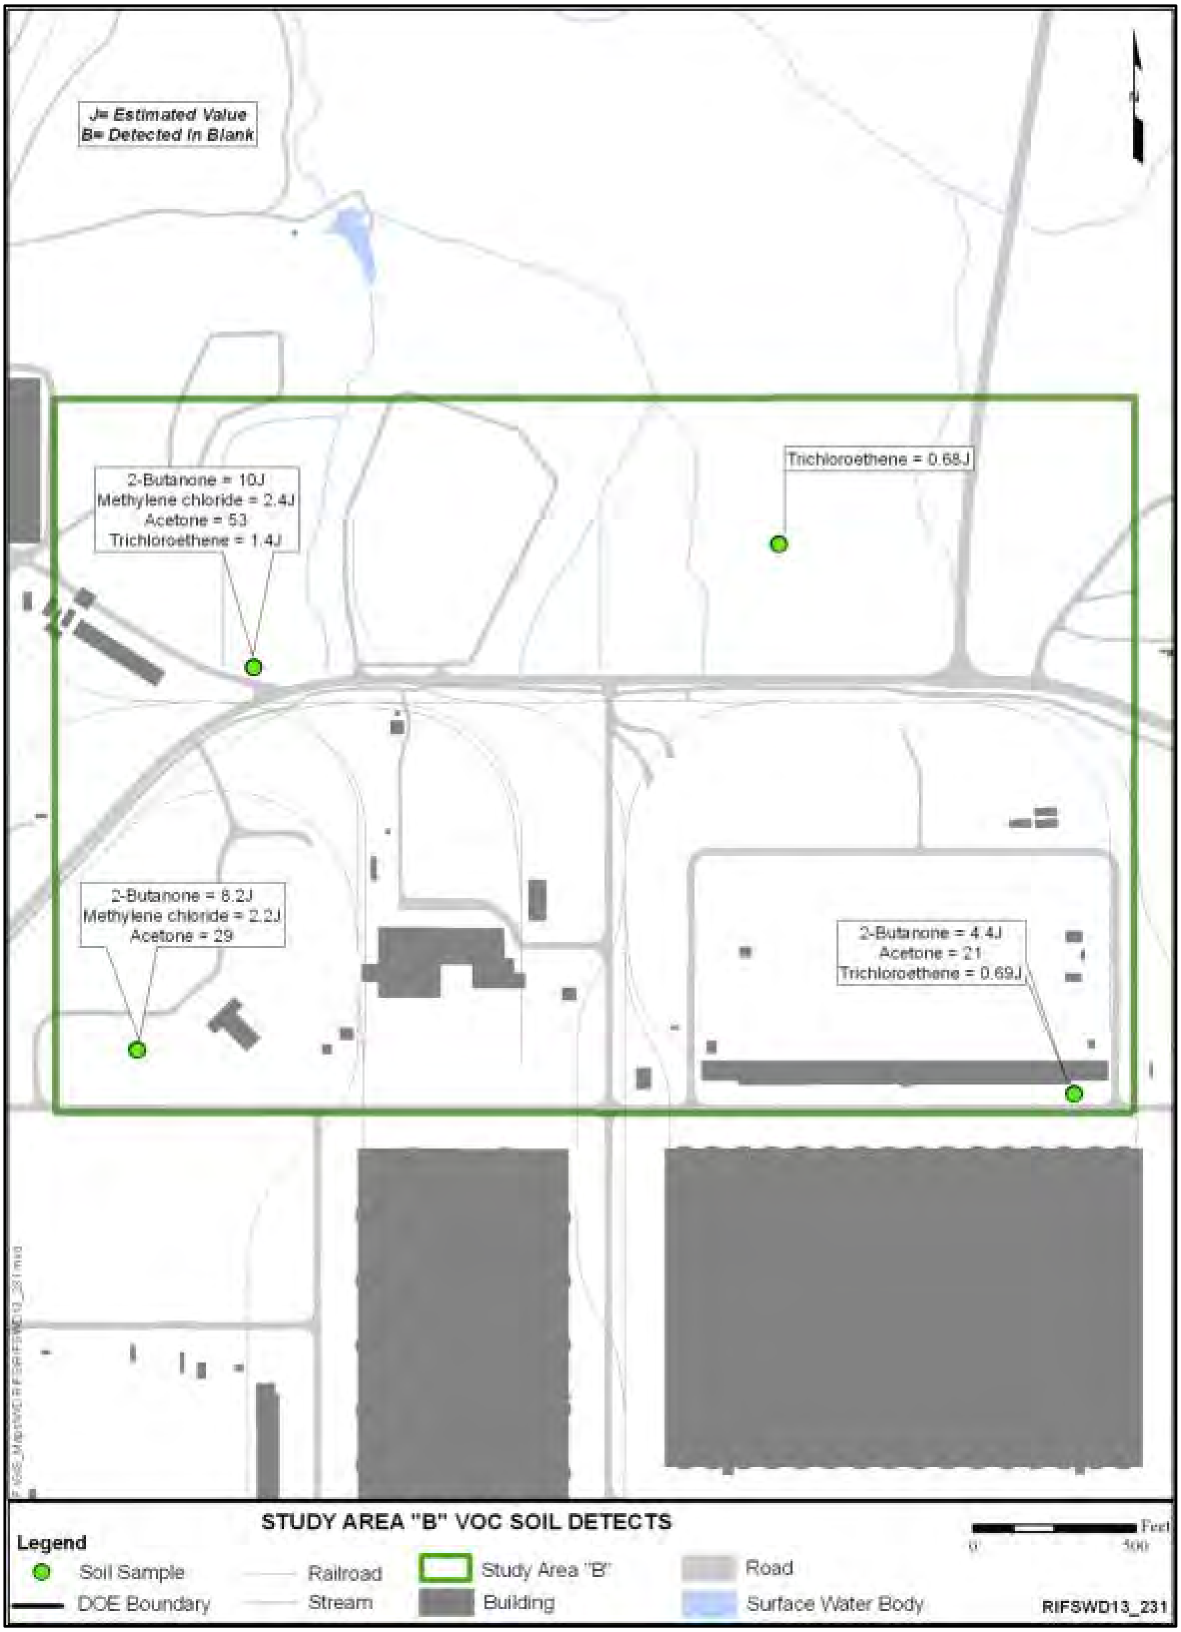

Figure 2.32. VOCs Detected in Soils at Study Area B

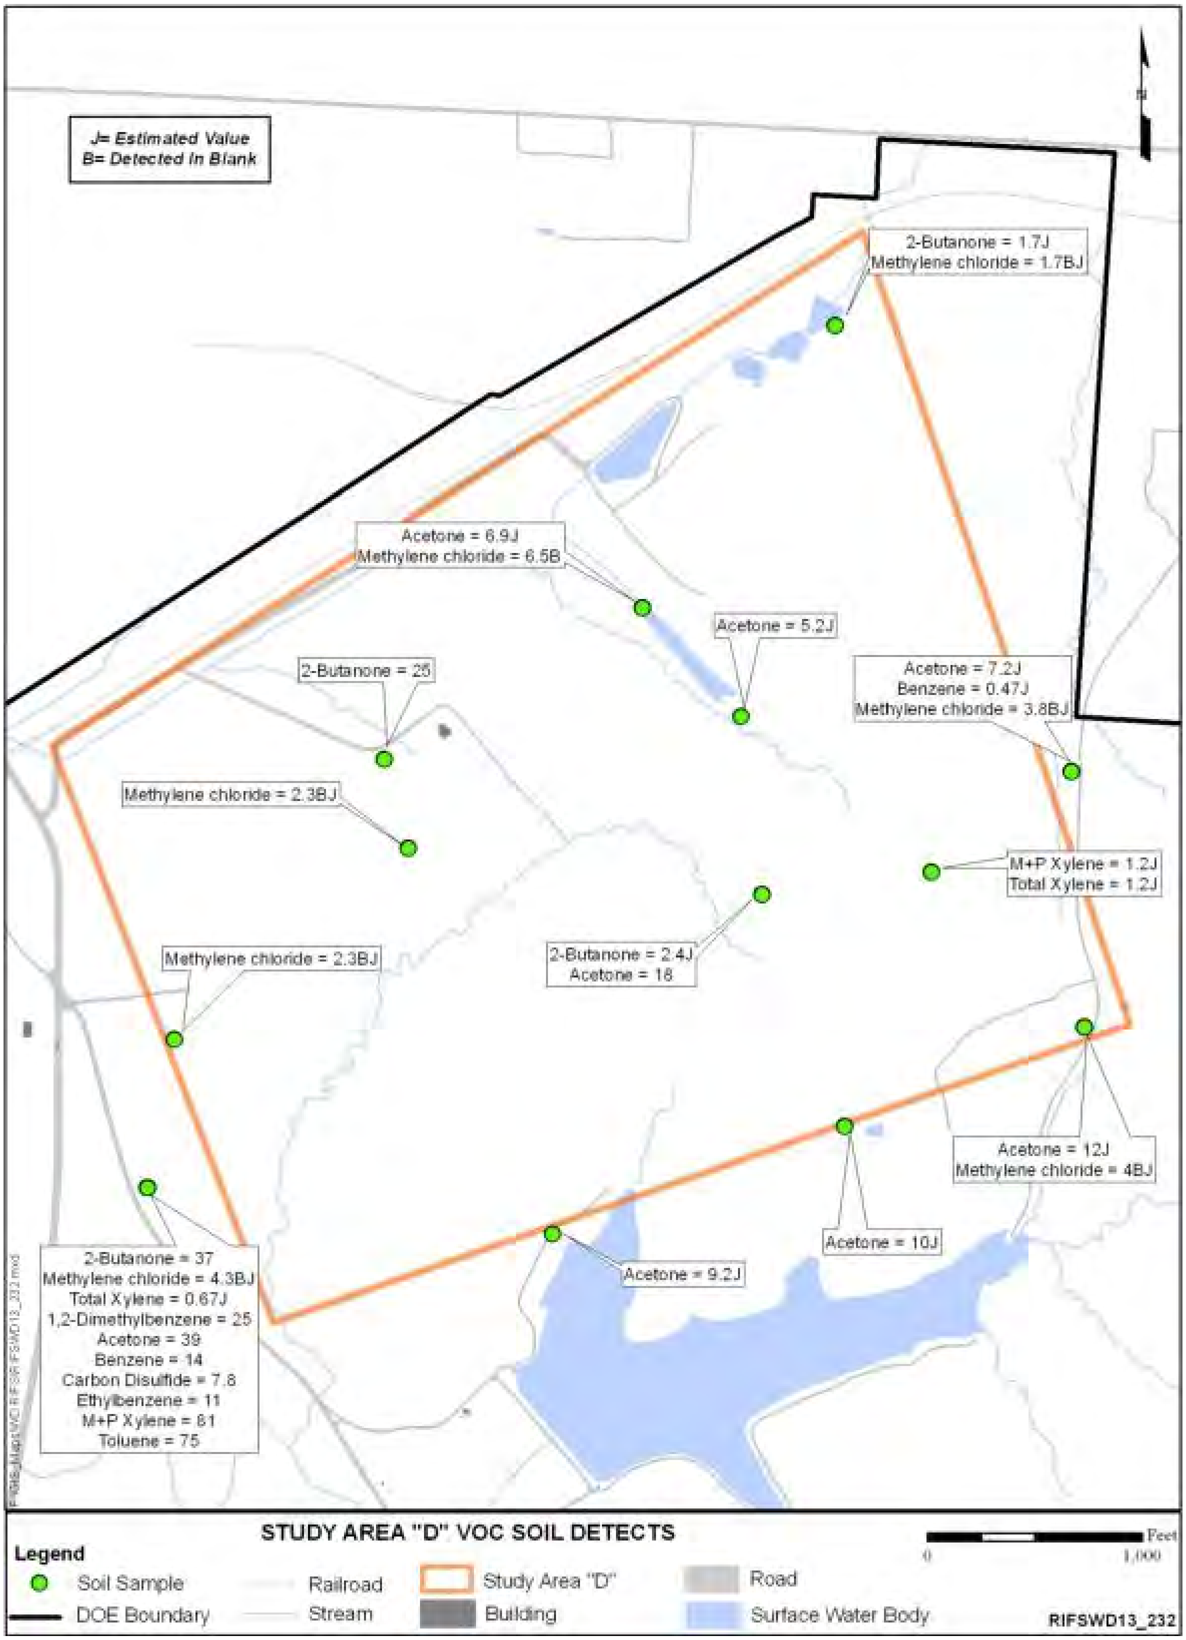

Figure 2.33. VOCs Detected in Soils at Study Area D

Geotechnical samples were collected to characterize the preliminary engineering properties (geotechnical properties) of the soil to allow an initial evaluation for the preliminary design of waste disposition alternatives. Most of the geotechnical samples were collected from the unconsolidated Minford/Gallia members of the Teays Formation and also the residual soils developed on bedrock.

Thirteen bedrock cores were also collected (primarily from the Cuyahoga Formation) for permeability and strength testing. Saturated vertical hydraulic conductivity was measured in all samples by using the flexible wall method. Tables 2.15 and 2.16 provide a summary of the vertical permeability results from the rock core samples.

Table 2.15. Vertical Saturated Hydraulic Conductivity Measurements for PORTS Rock Cores

Geotechnically, the unconsolidated soils consist primarily of over-consolidated lean clays and silts. A summary of the Atterberg limits from samples collected during this RI/FS is provided in Figure 2.34. This plot indicates the geotechnical properties of the unconsolidated soils (Minford silt and clay plus regolith overlying bedrock) are similar across the study areas with most results classified as inorganic clays of medium plasticity. The results for the regolith at Study Area D appear to have less variability than those at Study Area A, but the data are limited. The plastic limits of the soils are relatively constant with depth and average about 23 percent.

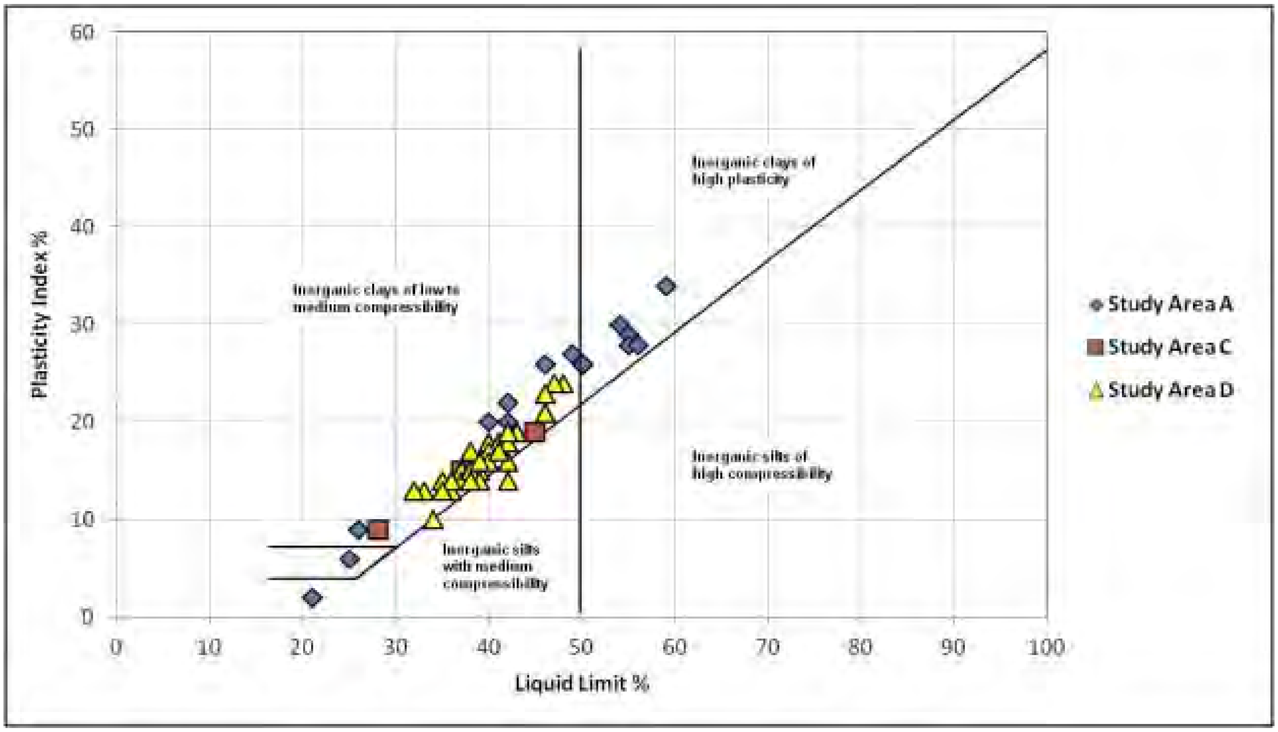

Figure 2.34. Atterberg Limits of Unconsolidated Soils Investigated in the RI/FS for PORTS

Moisture content is shown in Figure 2.35. The moisture content is typically higher in the soils at Study Area A (Minford) than in the soils at Study Areas C and D (regolith). There is a weak correlation of moisture content decreasing with depth (Figure 2.36), but the trend is not consistent in all borings.

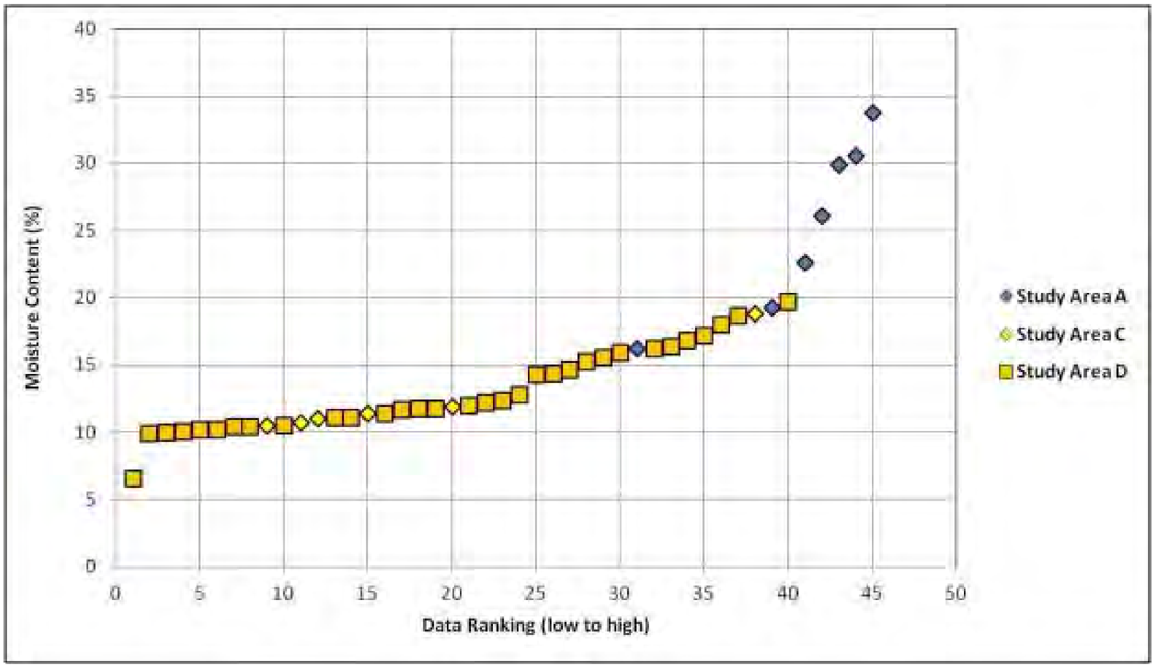

Figure 2.35. Moisture Content of Soils Investigated in the RI/FS for PORTS

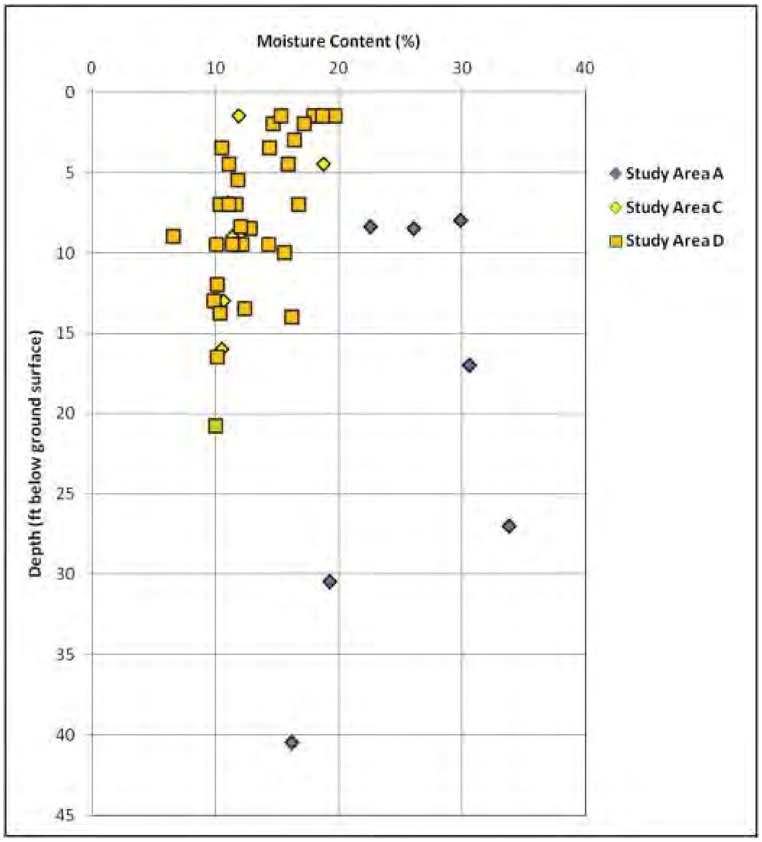

Figure 2.36. Moisture Content of Soils and Depth Below Ground Surface at PORTS

2.2.2.3 Surface water investigation

The approved Geotechnical SAP did not include any investigation of surface water. However, an Ohio EPA comment recommended a reconnaissance survey in Study Area D to determine if any seeps or springs are present and contributing to surface water in that area. A field change order was made to document the addition of a limited surface water investigation. An evaluation of two well-defined, intermittent/ephemeral tributaries was initiated in December 2011 to look for seeps and springs. Both of the intermittent streams are shown on U.S. Geological Survey 1:24,000 topographic maps. One of the streams runs southwest near the X-114A New Firing Range and discharges into Little Beaver Creek while the other runs north along the DOE property boundary and discharges into Big Beaver Creek.

Figure 2.37 shows the location of 56 seeps identified in Study Area D. Table 2.17 provides the seep locations and elevations. Eight seep locations were monitored over a 12-week period from mid-December 2011 through early March 2012 to evaluate seepage rates. Table 2.18 provides estimated flow rates for these eight seeps as well as their estimated elevations. Seeps OSDC-SP-4 and OSDC-SP-6, while recognized based on amount of soil moisture, did not have measurable flow rates. Seep OSDC-SP-8, located on the tributary valley east of Study Area D, had the greatest observed flow. These seeps appear ephemeral in nature and primarily occur as interflow and/or throughflow (i.e., subsurface stormflow) following precipitation events. Water that infiltrates into the regolith migrates laterally a relatively short distance and discharges on hillsides as ephemeral seeps (throughflow returning as wet weather conveyances) or directly into streams (interflow). The data indicates little seepage unless rainfall has occurred within a few days of measurement. Significant rainfall (> 0.5 in. over a 24-hour period) occurred prior to measurements on December 22, 2011; December 29, 2011; January 19, 2012; and March 1, 2012.

Based on the variability of the seep elevations, most of the seeps do not appear to be associated with any particular sandstone lenses or layers but are generally found at the interface above the weathered bedrock surface. In some instances, groundwater may discharge either from sandstone lenses or bedding plane partings in the weathered bedrock to create seeps along the hillside. Of the 56 seeps identified to date, fewer than 10 appear to be related to specific sandstone layers (either the 720-ft sandstone lenses or the 680-ft sandstone layer).

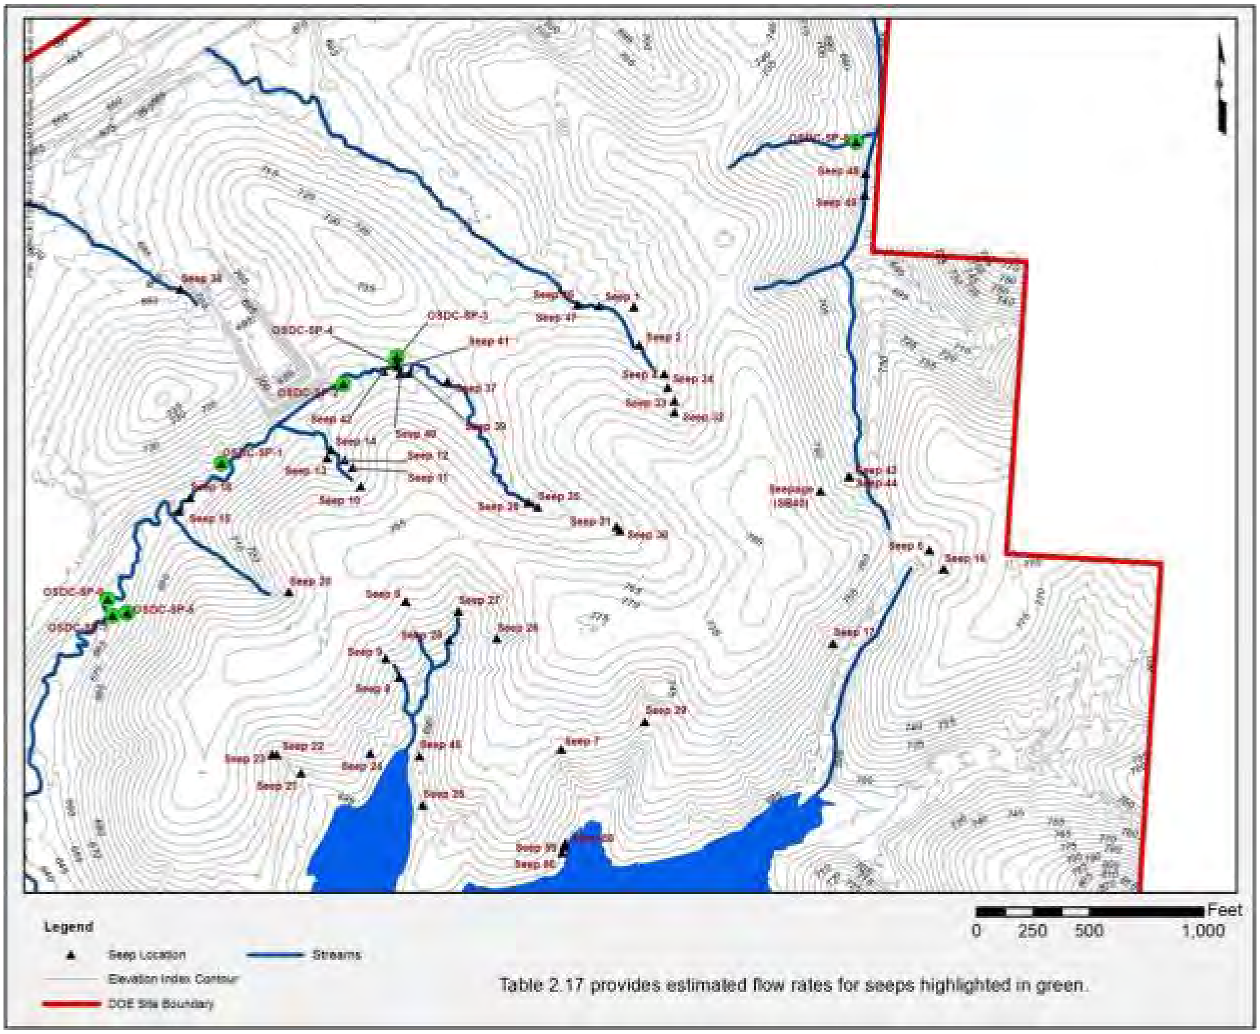

Table 2.17 provides estimated flow rates for seeps highlighted in green.

Figure 2.37. Seeps Identified at Study Area D

Table 2.17. Seep Locations and Elevations

Seep ID	State Plane-Easting	State Plane-Northing	Elevation (ft AMSL)
seep 1	1,831,765.0	377,786.3	719.6
seep 2	1,831,786.2	377,619.4	723.2

On April 9-10, 2012, a Level 1 Assessment of the physical habitat and geomorphic characteristics of several streams in Study Area D was performed by DOE. A total of eight Primary Headwater Habitat (PHWH) stream systems were initially identified during the Level 1 Assessment with a total of 22 individual streams present within Study Area D (Figure 2.38). The stream discussed above, south and southwest of the X-114A New Firing Range (Stream 1 in Figure 2.38), was classified as a probable Class III PHWH in a 1,672-ft reach downstream of the firing range. The rest of the stream within Study Area D, approximately 1,250 ft, was preliminarily identified in the study as a Class II interstitial PHWH stream system. Because of the potential presence of Class III PHWH streams in Study Area D, a Level 2 Assessment was performed to support a final determination of stream classification.

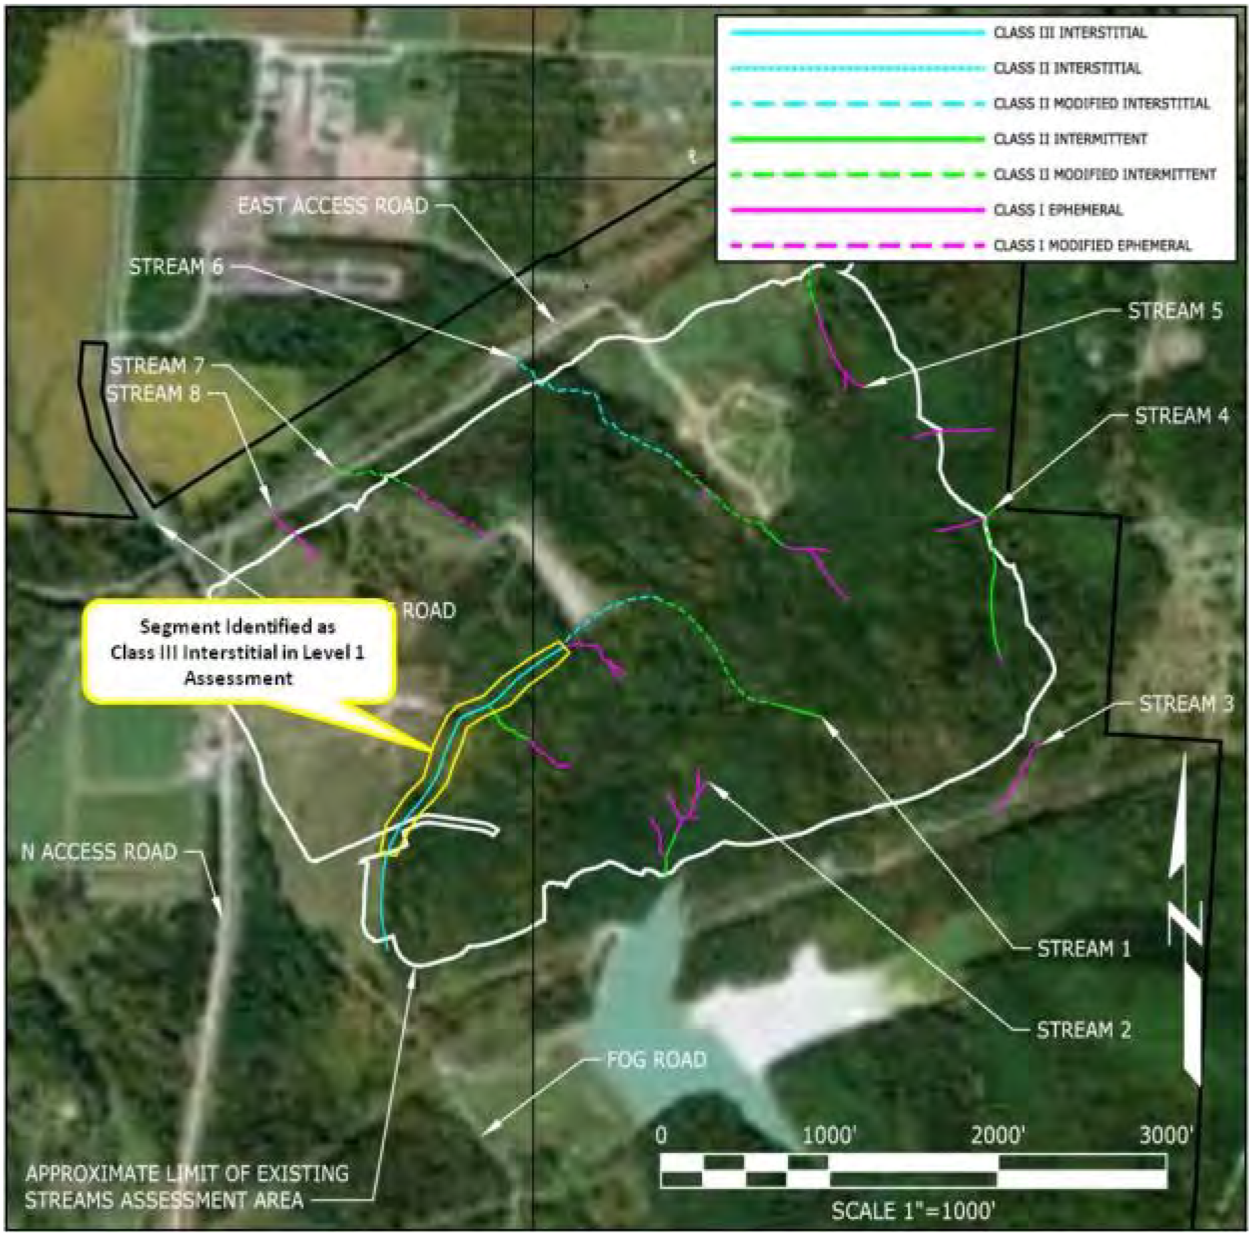

Figure 2.38. Stream Valleys Evaluated for Physical Habitat During a Level 1 Assessment at Study Area D

A more detailed assessment was performed in 2013. Stream assessments were conducted using methods described in Ohio EPA's *Field Evaluation Manual for Ohio's Primary Headwater Habitat Streams* (Version 3.0) (Ohio EPA 2012b) and *Methods for Assessing Habitat in Flowing Waters: Using the Qualitative Habitat Evaluation Index (QHEI)* (Ohio EPA 2006a). These assessments consisted of first conducting detailed physical assessments of each stream feature surveyed, including basic water quality measurements, global positioning system data, and photographs. The assessed reach of each stream was selected on the basis of a representative habitat location, excluding external influences such as culverts or tributaries. If streams showed significant changes in physical conditions throughout the length, an assessment was conducted in two locations.

Stream sites meeting specific habitat conditions (as defined in the Ohio EPA manuals) or observed to host larval salamanders were further assessed for biological communities by using a Level 2 or 3 Assessment. A Level 2 Assessment (Headwater Macroinvertebrate Field Evaluation Index [HMFEI]) was performed on the basis of location habitat characteristics that included a natural or recovered channel; stream flowing at the time of assessment; 10 percent or greater amount of cobble, bedrock, boulder or boulder slabs substrate; and a headwater habitat evaluation index score between 50 and 70. Level 3 Assessment included the salamander Visual Encounter Survey and Lowest Taxonomic Level Analysis for benthic invertebrates and was conducted at locations that exhibited Class III PHWH characteristics. This level of assessment positively differentiates between Class IIIA and IIIB communities.

Table 2.19 lists the 38 streams that were identified in Study Area D. One stream is a U.S. Geological Survey-named feature (Little Beaver Creek), and the remaining ones are unnamed tributaries to either Little Beaver Creek (23 streams) or Big Beaver Creek (14 streams). Ten streams were assessed using the HMFEI, including six that had a Level 3 Assessment. Little Beaver Creek has a Warmwater Habitat classification. Three reaches in Study Area D have a Class IIIA designation (UT 7, UT 9, and UT 36). All other streams were classified as lower to moderate quality Class I and Class II PHWHs. Figure 2.39 presents the locations and classifications of the various streams. It should be noted that there were no coldwater fish, salamanders, macroinvertebrate assemblages, or HMFEI scores that would indicate coldwater habitat. There were also no obvious field indicators of a predominantly groundwater influence. In conclusion, there are no streams in the study area that have been assigned a provisional Class IIIB PHWH classification. However, if Study Area D is selected for a potential OSDC, there are streams that lie within 200 ft of proposed waste boundaries.

A wetlands study was completed for Study Area D. The wetlands survey was conducted using methods described in the U.S. Army Corps of Engineers'(USACE's) *Corps of Engineers Wetland Delineation Manual* and the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Eastern Mountains and Piedmont Region* (Version 2.0). The approach is presented in DOE (2013b). Potential wetlands were identified in the field and then assessed using the Ohio Rapid Assessment Method for Wetlands, (Version 5.0). The locations and categories of the identified wetlands are presented in Figure 2.40. A list of the 24 wetlands is presented in Table 2.20.

Wetlands assigned to Category 1 support minimal wildlife habitat and minimal hydrological and recreational functions. They do not provide critical habitat for threatened or endangered species or contain rare, threatened, or endangered species. Such wetlands are categorized as “limited quality waters” under the Ohio EPA antidegradation rule, *OAC* 3745-1-05. Wetlands assigned to Category 2 support moderate wildlife habitat or hydrological or recreational functions and may include wetlands dominated by native species, but generally without the presence of, or habitat for, rare, threatened, or endangered species. No Category 3 wetlands, which have a higher quality, were found.

2.2.2.4 Test pits

One deviation from the Geotechnical SAP was the addition of two test pits in Study Area D. To facilitate observation of existing bedrock fracturing and depth of weathering in the Cuyahoga Formation, and to document the rippability of the bedrock, a test pit was excavated in Study Area D. To minimize the disturbance of bedrock features, a rock trencher was used at Test Pit 1 to cut two vertical trenches in the bedrock (Cuyahoga shale) prior to excavating the rock between the trenches. Two parallel, 50-ft-long trenches were initially cut into the exposed rock surface to a depth of 4 ft. The trenches were 15 ft apart and ran in an east-west direction. A bulldozer was initially used to rip the 2-ft-thick sandstone, which was at the surface in the trench area; however, the equipment could not penetrate deep enough to remove the sandstone. A large excavator was used to dig out the 2-ft-thick sandstone layer. The bulldozer was used to remove the shale in 6- to 12-in. increments, using only the blade. Excavation with the dozer blade continued to a depth of 4 ft where a 4-in.-thick sandstone layer was observed.

The trenches that were previously dug to 4 ft were then deepened an additional 4 ft for a total depth of 8 ft on the north and south sides of the test pit. The shale from between the trenches was then removed using the blade of the bulldozer in 6- to 12-in. increments. Excavation continued to a depth of 8 ft below the surface, coinciding with the depth of the two trenches.

Excavation then continued down to a total depth of 12 ft below the existing grade without any further trenching. The final excavation was performed only with the bulldozer. To reach a depth of 12 ft, the bulldozer operator used a ripper attachment to remove the shale as the bedrock was becoming more difficult to remove using only the blade.

For Test Pit 2, the excavation of the test pit was performed using an excavator only. The width of the test pit was approximately the width of the excavator bucket, and the final depth was approximately 20 ft. A video camera was lowered into Test Pit 2 to allow close-up observation of the soil and rock layers.

Observations from the test pits included the following:

- Fractures seen on the surface of the 2-ft-thick sandstone in the Cuyahoga Formation continued throughout the thickness of the sandstone layer but did not extend into the underlying shale. Fractures in the 2-ft-thick sandstone layer also contained clayey soil, approximately 0.5 in. thick. Test Pit 2 did not extend to the depth of the 2-ft-thick sandstone layer but encountered a shallower, approximately 4-in.-thick sandstone layer with similar fractures.

- In Test Pit 1, a 4-in.-thick sandstone layer was observed at a depth of approximately 4 ft (2 ft below the 2-ft-thick sandstone layer). It was fractured in a fairly regular pattern with each piece exhibiting an average diameter of approximately 12 in. This layer was easily broken with the ripper attachment.

- Observed fractures and/or joints were limited to the more brittle sandstone layers. No fractures or joints were observed in the shale.

- The degree of weathering of the shale, as expected, diminished with depth. The moisture content of the shale was observed to be higher near the surface and decreased with depth.

- The bulldozer could easily remove the shale to a depth of 8 ft with the blade only, but needed a ripper attachment to go deeper. At Test Pit 2, an excavator was used and was able to excavate to a depth near the maximum reach of the machine.

2.3 DEVIATIONS FROM THE SAMPLING PLAN

Deviations between actual field sampling activities and the activities proposed in the Geotechnical SAP have been formally tracked and authorized during the entire RI/FS sampling program for the Site-wide Waste Disposition Evaluation Project by using field change notices. Deviations include such things as additional samples, additional piezometers, and the addition of other media for investigation during the sampling program. General field changes include changes in the constituent list for a specific medium or changes in sampling protocols. All field change notices were reviewed and concurred with by Ohio EPA in order to maintain the integrity of data quality.

Some of the field change notices documented during field implementation of the SAP include the following:

- Having both total (unfiltered) and dissolved (filtered) metal samples collected and analyzed.

- Using an acoustic televiewer logging tool at Study Area D in selected soil borings to investigate the possible existence of fractures in the bedrock. The acoustic televiewer log provides an oriented, high-resolution image of the borehole using high-frequency acoustic sound waves as a source. Results from this tool provide location and orientation information for features such as fractures and lithologic contacts.

- Addition of a surface water walkdown of two intermittent tributaries in Study Area D to look for seeps and/or springs.

- Addition of two test pits near the OSDC Study Area D footprint to facilitate observation of existing bedrock fracturing and depth of weathering in the Cuyahoga Formation.

- Addition of three Cuyahoga piezometers (WD-PZ12C, WD-PZ13C, and WD-PZ14C) installed adjacent to three Berea monitoring wells to serve as well pairs in Study Area D.

- Hydraulic testing using existing monitoring wells/piezometers at Study Area D to determine site-specific hydrogeologic characteristics.

- Conversion of several open-hole piezometers in Study Area D into discretely screened piezometers to evaluate the 680-ft sandstone layer potentiometric surface.

2.4 QUALITY ASSURANCE/QUALITY CONTROL

QC was monitored throughout the RI process. QC included field sampling, laboratory analysis, and data management.

2.4.1 Field Quality Control

Field QC samples were collected to assess data quality. Table 2.21 lists the QC samples collected for each study area. The target collection frequency of QC samples for the entire project was 1 in 20 for equipment rinsates, field blanks, and field duplicates, as defined in Section 5.3.2.6 of the Geotechnical SAP. Overall, this target was met for the project. Trip blanks were collected at a frequency of one per sample cooler containing VOC samples.

Table 2.21. Summary of QA/QC Samples Collected during the RI at PORTS

Study Area	QC Sample Type	Frequency of Collection[a]
A	Equipment Rinsates	2/33
	Trip Blanks	6/33
	Field Blanks	4/33
	Field Duplicates	5/33

	Field Blanks	9/121
	Field Duplicates	6/121
Summary	Equipment Rinsates	17/281
	Trip Blanks	45/281
	Field Blanks	20/281
	Field Duplicates	19/281

[a] Frequency of collection is the number of QA/QC samples collected per number of regular samples (per interval) collected.

QA = quality assurance
QC = quality control

2.4.2 Laboratory Quality Control

Contract laboratories performed all of the analyses on soil and groundwater samples for the waste disposition RI. The laboratories performing the analyses were DOE-approved laboratories audited for compliance with requirements. Approved EPA SW-846 methods were used for all samples, except for those parameters that required other methods. Filtered and unfiltered analyses were performed on metals and uranium isotopes. All other analyses were performed using unfiltered samples.

The following analytical data qualifiers were used for reporting fixed-base laboratory results:

<u>Inorganic Analysis</u>

B This qualifier is used when the value is less than the Contract Required Detection Limit or Required Reporting Limit specified, but greater than or equal to the Instrument Detection Limit/Method Detection Limit.

U The analyte was analyzed for but not detected.

J	This qualifier indicates an estimated value.
E	The reported value is estimated because of the presence of interference. An explanatory note must be included under comments.
M	Duplicate injection precision was not met.
N	Spiked sample recovery was not within control limits.

Organic Analysis

U	Indicates compound was analyzed for but not detected.
J	This qualifier indicates an estimated value. It is used under the following circumstances: (1) when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed and (2) when the mass spectral and retention time data indicate the presence of a compound that meets the pesticide/PCB identification criteria, and the result is less than the contract-required quantitation limit, but greater than zero.
B	This qualifier is used when the analyte is found in the associated blank as well as in the sample.
E	This qualifier identifies compounds whose concentrations exceed the calibration range of the gas chromatograph/mass spectrometer instrument for that specific analysis.
Y	This qualifier indicates matrix spike/matrix spike duplicate recovery and/or relative percent difference (RPD) failed to meet acceptance criteria.

Radionuclide Analysis

B	Method blank was not statistically different from sample at a 95 percent level of confidence.
U	Compound was analyzed for but not detected.
J	This qualifier indicates an estimated value.
X	Other specific qualifiers may be required to properly define the results.
D	Sample is statistically different from duplicate at a 95 percent level of confidence.
L	Expected and measured value for laboratory control sample is statistically different at a 95 percent level of confidence.
M	Expected and measured value for matrix spike is statistically different at a 95 percent level of confidence.

Precision, accuracy, and completeness objectives were presented in Tables B.2 and B.3 of the Geotechnical SAP (DOE 2011a).

Precision refers to the level of agreement among repeated measurements of the same characteristic, usually under a given set of conditions. To determine the precision of the laboratory analysis, a routine program of replicate analyses is performed. The absolute difference between the two calculated values is referred to as the RPD. Precision is determined for this RI by reviewing laboratory-applied qualifiers that pertain to laboratory duplicates (“M” and “*” for inorganic analyses, “Y” for organic analyses, and “D” for radionuclide analyses) over all analyses. The QA objectives for precision given in the Geotechnical SAP are performance-based with RPDs that ranged from 13 to 50 percent.

Accuracy refers to the nearness of a measurement to an accepted reference or true value. To determine the accuracy of an analytical method and/or the laboratory analysis, a periodic program of sample spiking is conducted. Accuracy for this RI is determined by reviewing laboratory-applied qualifiers that pertain to laboratory spikes over all analyses (“N” and “W” for inorganic analyses; “Y” for organic analyses; and “B,” “M,” and “L” for radionuclide analyses). The accuracy range objective specified in the work plan was 80 to 100 percent.

Representativeness is the degree to which discrete samples accurately and precisely reflect a characteristic of a population, variations at a sampling location, or an environmental condition. Representativeness is a qualitative parameter and will be achieved through careful, informed selection of sampling locations, drilling locations, drilling depths, and analytical parameters, and through the proper collection and handling of samples to avoid interference and minimize contamination and sample loss.

Completeness is a measure of the percentage of valid, viable data obtained from a measurement system compared with the amount expected under normal conditions. The goal of completeness is to generate a sufficient amount of valid data to satisfy project needs. For this project, the completeness objective for laboratory measurements is 90 percent. Completeness is also a measure of samples collected during the field effort with respect to those targeted for collection in the SAP. The Geotechnical SAP called for collecting 181 soil samples for chemical analyses and 24 soil samples for geochemical analyses. The actual soil samples collected were 281 analytical samples and 56 geochemical samples; therefore, all soil samples targeted for chemical analysis during this RI were collected. Groundwater sample objectives were also fulfilled.

Comparability is the extent to which comparisons among different measurements of the same quantity or quality will yield valid conclusions. Comparability is assessed in terms of field standard operating procedures, analytical methods, QC, and data reporting. In addition, data validation assesses the laboratory processes that affect data comparability.

2.4.3 Data Management

The PORTS Project Environmental Measurements System (PEMS) was used to manage field-generated data; import laboratory-generated data; add data qualifiers based on data verification, validation, and assessment; and transfer data to the PORTS Data Warehouse. PEMS included a tracking system to identify, track, and monitor each sample and associated data from point of collection through final data reporting. The system included field measurements and chain-of-custody information.

All data packages and electronic data deliverables received from the laboratory were tracked, reviewed, and maintained in a secure environment. The following information was tracked: sample delivery group numbers, date received, document control number, number of samples, sample analyses, receipt of electronic data deliverables, and comments.

The data verification processes for laboratory data were implemented for both hard-copy data and electronic data deliverables. The data packages were reviewed to confirm that all samples had been analyzed for the requested parameters. Discrepancies were reported to the laboratory and data validators. As part of a series of internal integrity checks within PEMS, a check was run to identify which of the requested samples and analyses were not received in an electronic data deliverable.

Data verification within PEMS included standardization of analytical methods, chemical names and units, and checks for holding time violations and detections above background values. The security of PEMS and the data used for the data management effort were considered to be essential to the success of the project. Access to PEMS was limited, on an as-needed basis, to the data management personnel. Read-write, graded access to PEMS was limited to the data management team. The data management staff assisted other project members with data needs from PEMS by running requested queries.

Data validation is a process performed for a dataset by a qualified individual independent from sampling, laboratory, project management, and other decision-making personnel for the project. Data validation is performed in accordance with EPA guidance. In the data validation process, laboratory adherence to analytical method requirements is evaluated.

As part of the data review process, findings were qualified (as necessary) to reflect data validation results. The following validation qualifiers were assigned by the data validators:

N	The analysis indicates the presence of an analyte for which there is presumptive evidence to make a tentative identification.
U	Analyte or compound was considered not detected above the reported detection limit.
J	Analyte or compound was identified; the associated numerical value is approximated.
UJ	Analyte or compound not detected above the reported detection limit, and the reported detection limit is approximated because of quality deficiency.
R	Result is not usable for its intended purpose, so data are of “information only” quality and should be supplemented with additional data for decision making.
XV	Data were not validated; refer to the RSLTQUAL field, which may contain more information.
XZ	Data validation performed but no validation qualifier was applied; refer to the RSLTQUAL field which may contain more information.
=	Data were validated; however, no qualifier was added.

HIGHLIGHTS OF SECTION 2

- Considerable historical environmental media data have been collected at PORTS since the mid-1990s.
- On-PORTS soil and groundwater have been contaminated by historical releases and practices. Contaminants include radionuclides (primarily uranium and technetium), metals, and organics.
- Current data and groundwater remediation efforts indicate no off-PORTS contamination above regulatory standards.
- Recently collected data from the process equipment confirm technetium-99 and uranium deposits in the process equipment—greatest contamination is in X-326.
- Permeabilities, site-specific K_d values, and TOCs all contribute to low migration rates in the subsurface.
- A saturated sandstone layer was found below Study Area D at an average elevation 680 ft AMSL (10-40 ft bgs).
- There are numerous wetlands and streams throughout Study Area D. These surface water bodies have been classified according to State of Ohio guidance and protocol.

NEXT STEP: SECTION 3 PRESENTS THE OVERALL ENVIRONMENTAL SETTING OF PORTS

3. PHYSICAL CHARACTERISTICS OF THE STUDY AREA

Development of a CSM is an element of defining environmental problems. CSMs consist of understanding the nature and extent of contamination present, the fate of those contaminants in the environmental setting, and the potential location of receptors that use or may use the contaminated media. Development of a complete CSM and then defining the magnitude of the impact of the contaminants on receptors completes the problem definition.

Section 2 presented the data obtained from investigations, both historical and under this project, that are used in defining elements of the CSM. In Section 3, the information collected across PORTS is coalesced into an understanding of the physical features of PORTS that will have a bearing on the fate of contaminants, along with their transport mechanisms and the locations of potential current receptors and sensitive resources. The intent of Section 3 is to present a catalogue of PORTS conditions relative to surface features, meteorology, surface water hydrology, geology, hydrogeology, soils, demography and land use, and ecological resources. Each one of these subjects has a separate section of text. Section 3 provides the information that supports the conclusion that contaminants will not readily migrate off PORTS because of underlying hydrogeologic conditions and that the future potential uses of PORTS and surrounding areas are industrial and rural residential.

More specific information related to each of the candidate locations for a potential OSDC is presented in Appendix D.

3.1 SURFACE FEATURES

PORTS is located in Pike County in south central Ohio, east of the Scioto River, and within the Scioto River's drainage basin (Figure 3.1). It occupies an upland area of southern Ohio and has an average land surface elevation of 670 ft AMSL (with a range from approximately 555 to 850 ft AMSL). The plant sits in a 1-mile-wide ancestral river valley situated approximately 130 ft above the Scioto River floodplain, which lies to the west. In much of the industrialized area of PORTS, the original topography has been modified and graded for construction of buildings and other facility components. Much of the industrialized area is located on fill that was removed from higher elevations of the plant and placed in existing drainage valleys and depressions to make the plant more level.

The local topography at PORTS is dominated by ancient and recent streams. The predominant landform in the area is an undulating, broad, sediment-filled, ancestral river valley. This valley is oriented north-south and is bounded on the east and west by deeply dissected ridges and low-lying hills. The surface of the river valley is modified by recent streams (Figure 3.2). A small valley is formed by Little Beaver Creek, which flows in a northwesterly direction across the middle of the plant, just north and east of the main industrialized area. Other small valleys formed by streams have cut into the flat-lying, unconsolidated deposits on which PORTS is located. One of these valleys is that of a westward-flowing stream, West Drainage Ditch, which is near the west-central area of the plant. Two more streams are located in the southern portion of the industrialized area. In the southeast portion of the plant, the southerly flowing stream, Big Run Creek, is situated in a relatively broad, gently-sloping valley. The Southwest Drainage Ditch has formed a narrow, steep-walled valley. The topography of the four locations evaluated for a potential disposal cell is discussed in Appendix D.

3.2 METEOROLOGY

This section describes the climatology and meteorology in the area surrounding PORTS and also provides a discussion of air quality at the plant.

3.2.1 Regional Climatology

The climate of the PORTS area is humid-continental and is characterized by warm, humid summers and cold, humid winters. For the period of record (June 1893 to December 2010) in Waverly, Ohio (approximately 10 miles north of PORTS), the daily temperature averages are 73°F in the summer (June through August) and 33°F in the winter (December through February). The average annual temperature is 54°F. Record high and low temperatures are 107°F and -31°F, respectively (Western Regional Climate Center [WRCC] 2011).

Precipitation is distributed relatively evenly throughout the year and averages approximately 40 in. per year. The month with the highest average precipitation for the period of record (June 1893 to December 2010) is May, and June is the second. Groundwater recharge and flood potential are greatest during the spring. February is the driest month. Snowfall averages approximately 19 in. per year, and snowmelt is part of the total annual precipitation (WRCC 2011).

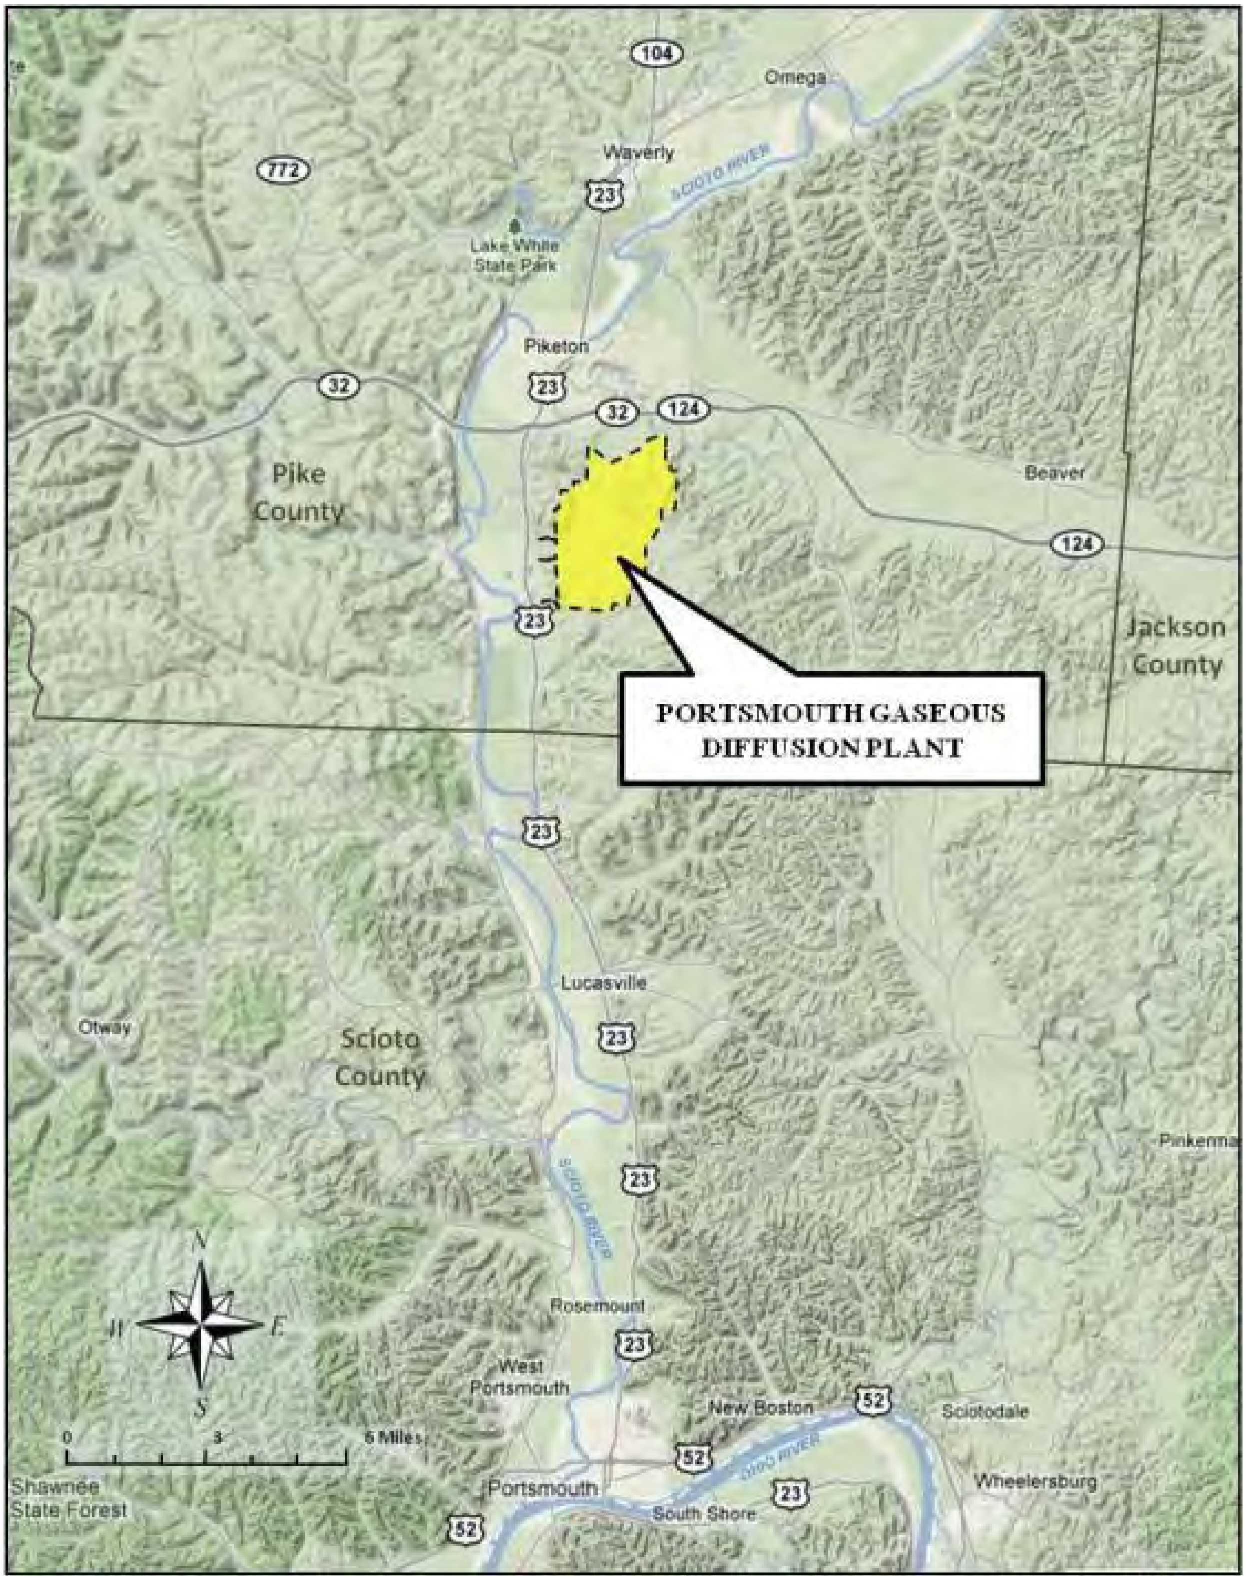

Figure 3.1. PORTS Location and Major Drainage

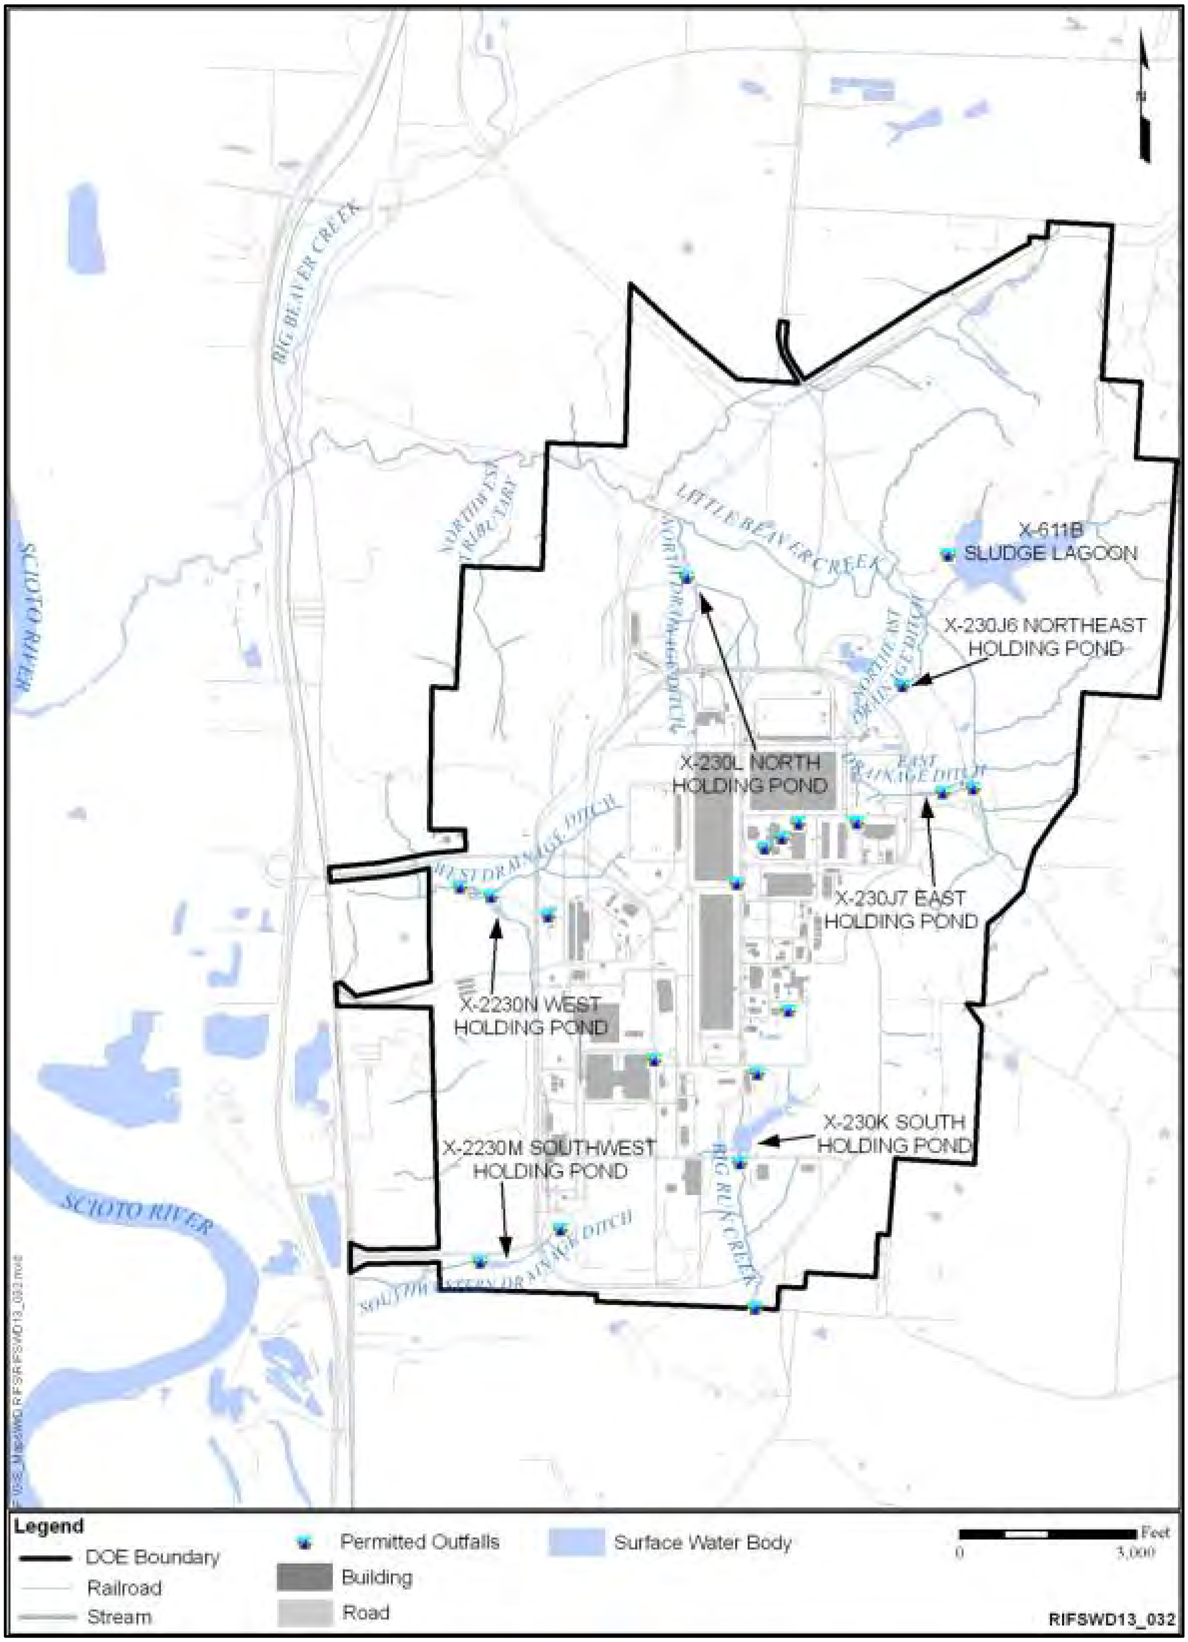

Figure 3.2. Surface Water Features at PORTS

Wind data have been collected at an on-PORTS meteorological tower. The data were collected at heights of 33, 98, and 197 ft above the ground surface. An evaluation of data collected from 1995 through 2001 indicated that winds at the 33-ft level appear to be influenced by local topographical and/or vegetative features, while the wind data from the 98-ft level are believed to be more representative (NRC 2006a). A wind rose of the 98-ft level from 1995 through 2001 is presented in Figure 3.3. About one third of the time, the wind blew from the south-southwest at an average speed of almost 6.5 mph. Directional wind speed was highest from the south at approximately 8 mph, while the lowest value was recorded in winds blowing from the east at 4 mph.

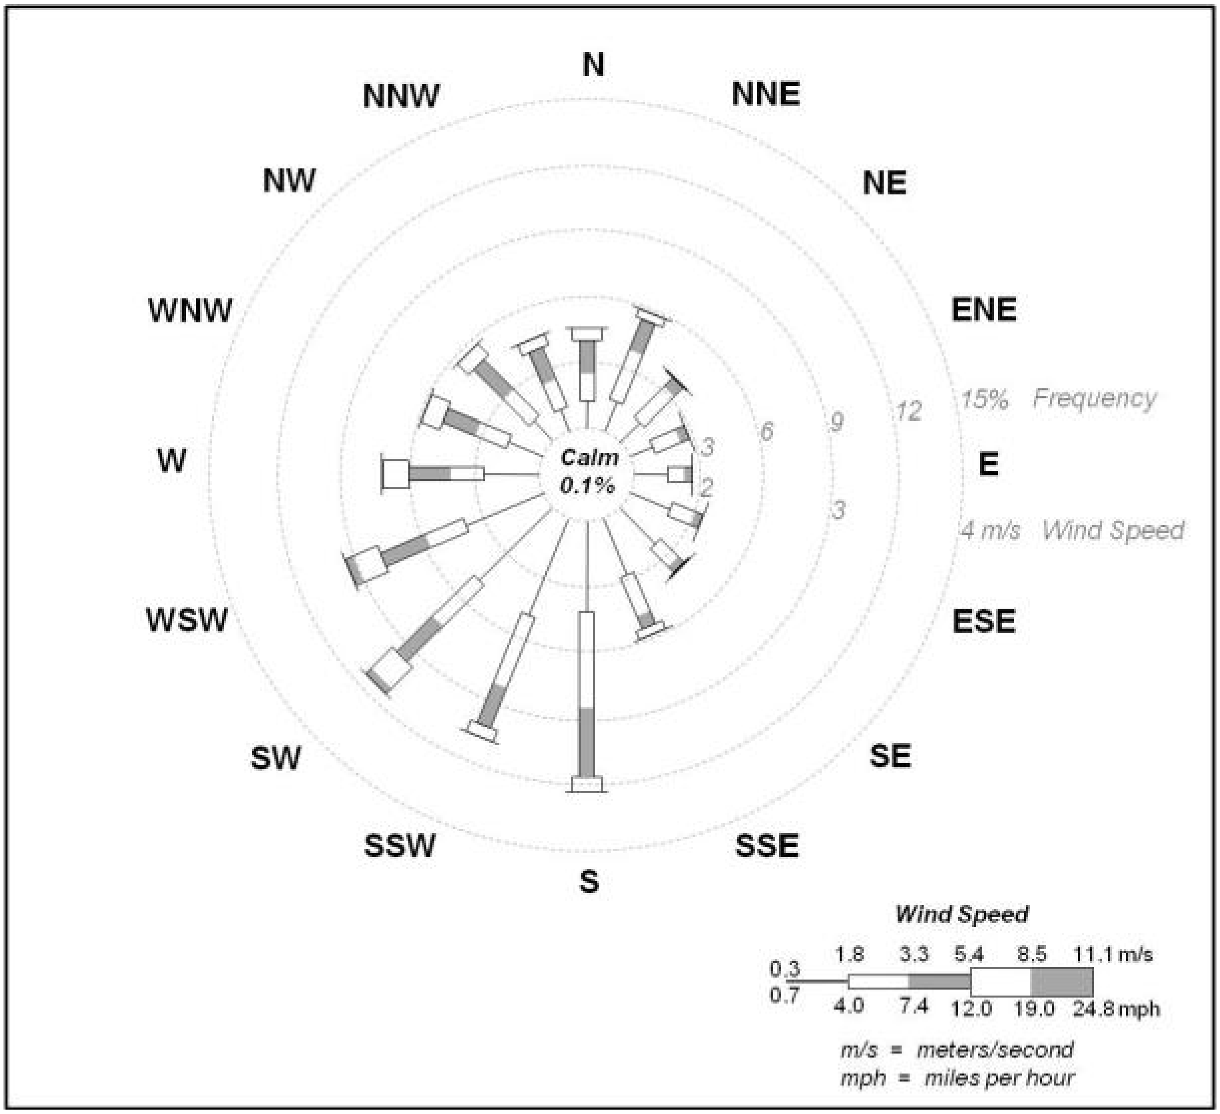

Figure 3.3. Wind Rose for PORTS

Tornadoes are rare in the area surrounding PORTS. For the period January 1950 through April 2011, 1,026 tornadoes were reported throughout Ohio, with an average of 15 tornadoes per year. While eight tornadoes were reported in Pike County during this period, all were F2 level or less (wind speeds less than 157 miles per hour) on the Fujita scale (National Climatic Data Center 2011).

3.2.2 Air Quality

The EPA has established maximum concentrations for pollutants in ambient air, referred to as the National Ambient Air Quality Standards (NAAQS). The Ohio State Ambient Air Quality Standards are identical to the NAAQS. Six criteria pollutants are used as indicators of air quality: ozone (O_3), carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), particulate matter with a mean diameter of 10 micrometers or less (PM_{10}), particulate matter with a mean diameter of 2.5 micrometers or less ($PM_{2.5}$), and lead. Areas in which ambient air concentrations meet the standards for each criteria pollutant are designated as attainment areas. Areas that do not meet the standards are designated as nonattainment areas. PORTS is located in the Wilmington-Chillicothe-Logan Intrastate Air Quality Control Region, which covers the south-central part of Ohio. Pike, Ross, and Jackson Counties are in attainment for all criteria air pollutants (40 *CFR* 81.336). Scioto County, south of PORTS, is a nonattainment area for $PM_{2.5}$ (EPA 2011a).

The DOE operations at PORTS generate conventional nonradiological air pollutants such as organic compounds and particulate matter. The air emission sources at PORTS include two landfill venting systems, one glove box, and four groundwater treatment facilities. Ohio EPA regulates these as minor sources. Other sources include the three boilers at the X-600 Steam Plant (which provide steam for PORTS), the X-6002 boilers, diesel engine compressors associated with the X-326 dry air systems, and gravel roads/parking lots associated with construction areas. Air emissions are estimated every 2 years for the Ohio EPA Biennial Emission Fee Statement. To calculate air emissions, PORTS assumes that each source emits the maximum allowable amount of each pollutant as provided in the permit or registration for each source. The following are 2009 emissions of nonradiological air pollutants from DOE operations at PORTS: 0.202 ton of lead, 48.9205 ton of particulate matter, 16.0003 ton of organic compounds, 2,051.16 ton of sulfur dioxide, and 225.666 ton of nitrogen oxides. More than 99 percent of these emissions were associated with the boilers, diesel engine compressors, and construction areas (DOE 2011d).

With regard to greenhouse gas emissions associated with PORTS, a significant source of CO_2 is employee transportation vehicles. The EPA estimates that each gallon of gasoline produces 19.4 lb of CO_2 emissions (EPA 2005). Assuming that each PORTS worker drives 30 miles roundtrip to and from work in a vehicle with a fuel economy rating of 20 miles per gallon of gasoline, each worker generates approximately 29 lb of CO_2 in their daily commute. Assuming a 5-day work week and 50 working weeks per year, the annual amount of CO_2 emissions by each worker is 7,300 lb (about 3.7 ton). Based on current plant employment (2,709, including DOE and tenants), approximately 9,888 ton of CO_2 is emitted annually from employee vehicles. In addition, in the 1950s, two coal-fired power generation plants (Kyger Creek in Ohio and Clifty Creek in Indiana) were originally dedicated to supplying electrical power to PORTS. Kyger Creek and Clifty Creek emitted a total of approximately 16 million ton of CO_2 in 2006 (SourceWatch 2011a; 2011b). In the same year, both plants generated a total of approximately 16.2 million megawatt-hours (MWh) of electricity (Ohio Valley Electric Corporation [OVEC] 2007). This equates to approximately 0.99 ton of CO_2 emitted per MWh. To support current annual electrical requirements at PORTS (approximately 250,000 MWh), approximately 247,500 ton of CO_2 are emitted. This amount, combined with the employee vehicle emissions, means the total CO_2 footprint of PORTS is approximately 257,400 ton per year.

DOE collects samples from 15 ambient air monitoring stations and analyzes them for radionuclides that could be present in ambient air as a result of PORTS activities. These radionuclides are isotopic uranium (uranium-233/234, uranium-235, uranium-236, and uranium-238), technetium-99, and selected transuranic radionuclides (americium-241, neptunium-237, plutonium-238, and plutonium-239/240). The ambient air monitoring stations measure radionuclides released from point sources, fugitive air emissions (emissions that are not associated with a specific release point such as a stack), and background levels of radiation (radiation that occurs naturally in the environment and is not associated with PORTS operations) (DOE 2011d).

Airborne discharges of radionuclides from the PORTS are regulated in accordance with 40 *CFR* 61, Subpart H, and the National Emission Standards for Hazardous Air Pollutants (NESHAPs). No transuranic radionuclides were detected in the samples collected from the ambient air stations in 2009. Technetium-99 was detected at Stations A23 (northeastern plant boundary) and A24 (north of the plant on Schuster Road). The maximum activity of technetium-99 in ambient air was 0.0031 pCi/m^3 at Station A24, which is well below the DOE-derived concentration guide of 2,000 pCi/m^3.

Uranium-233/234 and uranium-238 were detected in all of the 2009 samples, including those from background locations, which are established upward of plant operations. The highest average activity of uranium-233/234 (0.00083 pCi/m^3) was detected at Station A29 (on PORTS at OVEC). The highest average activity of uranium-238 (0.00073 pCi/m^3) was detected at Station A28 (southwest of PORTS on Camp Creek Road). These average activities are well below the DOE-derived concentration guides for uranium-233/234 (0.09 pCi/m^3) and uranium-238 (0.1 pCi/m^3).

3.3 SURFACE WATER HYDROLOGY

PORTS is drained by several small tributaries of the Scioto River (Figure 3.2). Sources of surface water drainage include storm water runoff, groundwater discharge, and effluent from plant processes. This section provides a description of the surface water and sediment characteristics for streams influenced by operations at PORTS.

The largest stream at PORTS is Little Beaver Creek, which runs approximately 4.5 miles from the east-central portion of the plant to the northwest DOE boundary. Little Beaver Creek receives drainage from the eastern and northern portions of PORTS before discharging into Big Beaver Creek. Little Beaver Creek is a small, high-gradient, unmodified stream that receives the majority of its flow from the X-230J7 East Holding Pond discharge through the East Drainage Ditch. Little Beaver Creek also receives effluent via the Northeast Drainage Ditch through the outfall from the X-230J6 Northeast Holding Pond and via the North Drainage Ditch through the outfall from the X-230L North Holding Pond.

Ohio EPA periodically assesses stream water quality at five locations along Little Beaver Creek. The lower 2.8 miles of the stream are fully attaining warm water habitat aquatic life biocriteria, with a portion of this (approximately 1.9 miles) characterized by exceptional biological quality. Substrates are predominantly slab boulders and bedrock at the upper reach to gravel and sand near the mouth of the stream. During parts of the year, intermittent flow conditions exist upstream from the X-230J7 discharge. During the summer/fall low-flow time of the year, the upstream section is composed of shallow, isolated pools with intermittent flow (Ohio EPA 2006b), which is a principal reason the upstream reach is not attaining warm water habitat aquatic life biocriteria. The Northwest Tributary stream corridor begins in the northwestern portion of the DOE property (Figure 3.2) and flows approximately 3,200 ft before leaving the PORTS property and prior to its confluence with Little Beaver Creek.

Water quality chemical characteristics are also evaluated during the Ohio EPA assessment. Most recently, the only exceedance of water quality criteria in Little Beaver Creek was for copper (Ohio EPA 2006b). The exceedance for copper appeared to be related to the very low hardness conditions recorded at the time of sampling. In general, all metals concentrations were very low with nearly half of the tested parameters less than the laboratory detection limits. VOCs and SVOCs were reported as not detected in the Ohio EPA assessment. However, DOE has detected TCE and *cis*-1,2-dichloroethene at low concentrations at DOE surface water sampling locations in Little Beaver

Creek on the plant (DOE 2011b). The pH levels in Little Beaver Creek, ranging from approximately 7.5 to 7.7 units, were within acceptable water quality limits. Dissolved oxygen measurements were indicative of good water quality with values varying from approximately 7.0 to 8.5 mg/L. Radiological results from sediments revealed elevated levels of technetium-99, total uranium, and isotopic uranium, but the levels were below ecological screening levels (Ohio EPA 2006b).

Big Run Creek is the smaller tributary of the Scioto River that drains the southern portion of PORTS. This stream receives outfall effluent from the X-230K South Holding Pond at its headwaters. Big Run Creek flows south-southwest from PORTS for approximately 4 miles until it intersects the Scioto River. The most upstream sampling location on Big Run Creek, located downstream of the outfall from the X-230K South Holding Pond, was in nonattainment of the warm water habitat aquatic life biocriteria (Ohio EPA 2006b). A sampling location at the PORTS boundary was in partial attainment, and full attainment was noted at another location approximately 0.3 miles downstream from the boundary. The substrates of Big Run Creek are predominantly gravel and cobble, and the stream channel remains unmodified. Because of the small stream size and high gradient, deep pools are absent (Ohio EPA 1993).

In Big Run Creek, surface water results for radiological parameters indicated that radiological doses, based on the activity concentrations measured, were within acceptable levels for protection of aquatic biological communities. Sediment sample results indicated low levels of metals and most organic chemicals. However, total PCBs were slightly elevated below the X-230K outfall. Radiological results from sediment samples were elevated, but they were below ecological screening benchmarks (Ohio EPA 2006b). The dissolved oxygen levels (ranging from approximately 6.5 to 7.5 mg/L) were slightly lower than those observed in Little Beaver Creek.

Because both Little Beaver Creek and Big Run Creek cut through unconsolidated material and intersect bedrock and the ancestral Portsmouth River Valley essentially forms a large “bowl” around PORTS, all groundwater leaving PORTS through unconsolidated deposits is eventually drained to the Scioto River by these two streams.

Two ditches drain the western and southwestern portions of PORTS. Flow in these ditches is low to intermittent. The West Drainage Ditch receives water from surface water runoff, storm sewers, and plant effluent. The Southwest Drainage Ditch receives water mainly from storm sewers and groundwater discharge. These two drainage ditches continue west and ultimately discharge into the Scioto River.

PORTS has 19 permitted outfalls (Figure 3.2) that discharge process water from the property (DOE 2010b). Eleven of these outfalls discharge directly to surface water while the others initially discharge to internal outfalls, such as the X-6619 Sewage Treatment Plant, before leaving the plant.

Floodplains consist of mostly level land that may be submerged by floodwaters along rivers and streams. The 1988 flood insurance rate map provided by the Federal Emergency Management Agency (FEMA) (FEMA 2009) indicates that the 100-year floodplain extends on both sides of Little Beaver Creek upstream from its confluence with Big Beaver Creek to the rail spur located near the X-230J9 North Environmental Sampling Station. The 100-year floodplain ranges on either side of Little Beaver Creek from 50 to 200 ft, roughly following the 575-ft topographic contour. Flooding is not a problem for the majority of the plant. The highest recorded flood level of the Scioto River in the vicinity of PORTS was 570 ft AMSL in January 1913, which is approximately 100 ft below the level of most PORTS facilities. No portion of the 100-year floodplain for Big Run Creek is located within the PORTS boundary.

The 1988 flood insurance rate map provided by FEMA indicates that no portion of PORTS, including the area of Little Beaver Creek, falls within the 500-year floodplain. This is likely a result of the deeply incised drainage and steep gradients along Little Beaver Creek, which would limit the area covered by the 500-year floodplain.

3.4 GEOLOGY

The geology of PORTS has been characterized over the years by the installation of more than 1,600 soil borings and wells across the plant. The information in this section was obtained primarily from the PORTS quadrant RFI final reports listed at the beginning of Section 3. The subsurface consists of approximately 30 to 40 ft of unconsolidated Quaternary clastic sediments (such as sand, silt, and clay) overlying Paleozoic bedrock that dips gently toward the east (Figure 3.4). In stratigraphic order, bedrock is overlain by fluvial Gallia sand and gravel (Gallia) and by the lacustrine Minford clay and silt (Minford) of the Teays Formation (Figure 3.5). The erosion and subsequent fill of the Portsmouth River Valley during the Pleistocene is a primary factor controlling the shallow geologic units beneath PORTS. A portion of the ancestral Portsmouth River Valley underlies the plant.

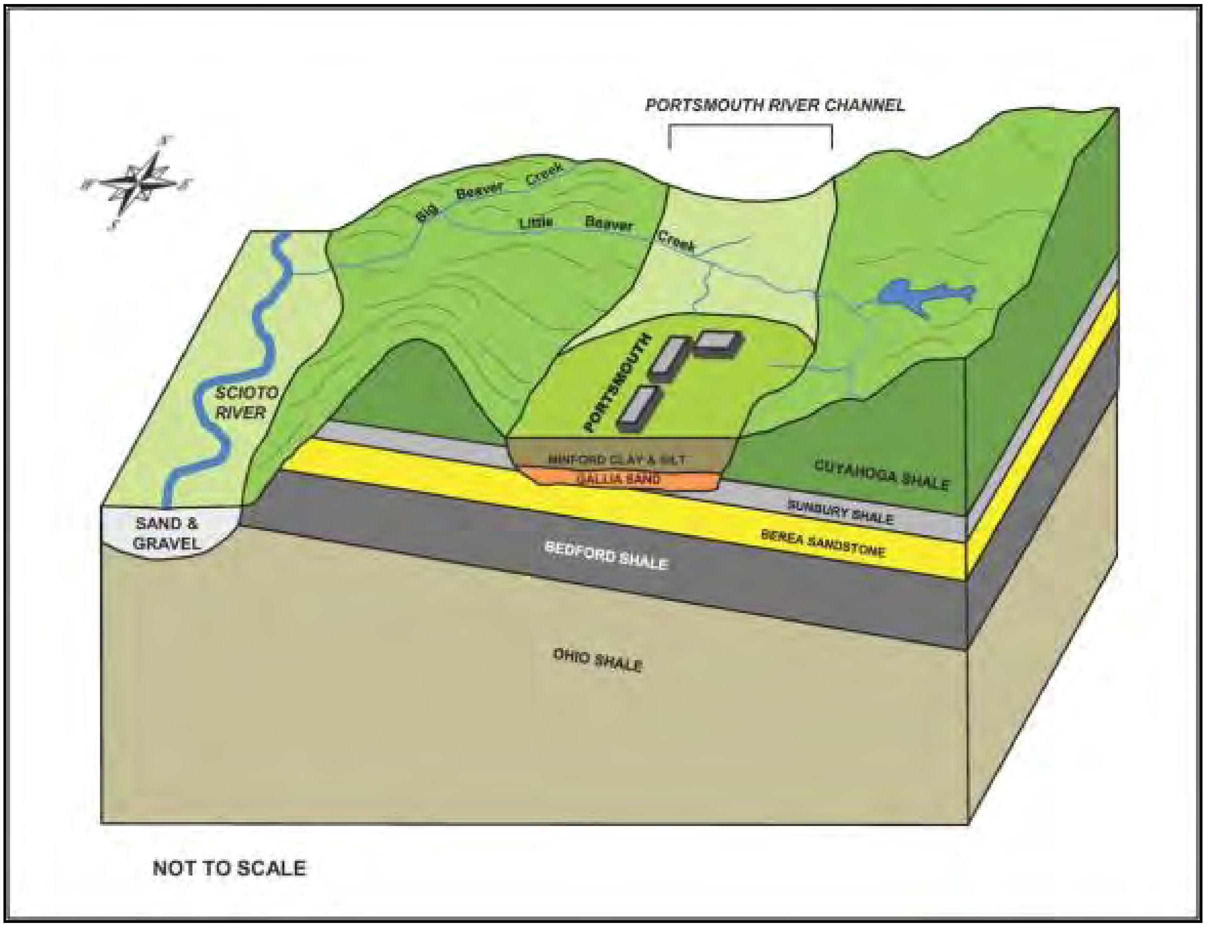

Figure 3.4. Schematic Block Diagram Showing Geological Relationships at PORTS

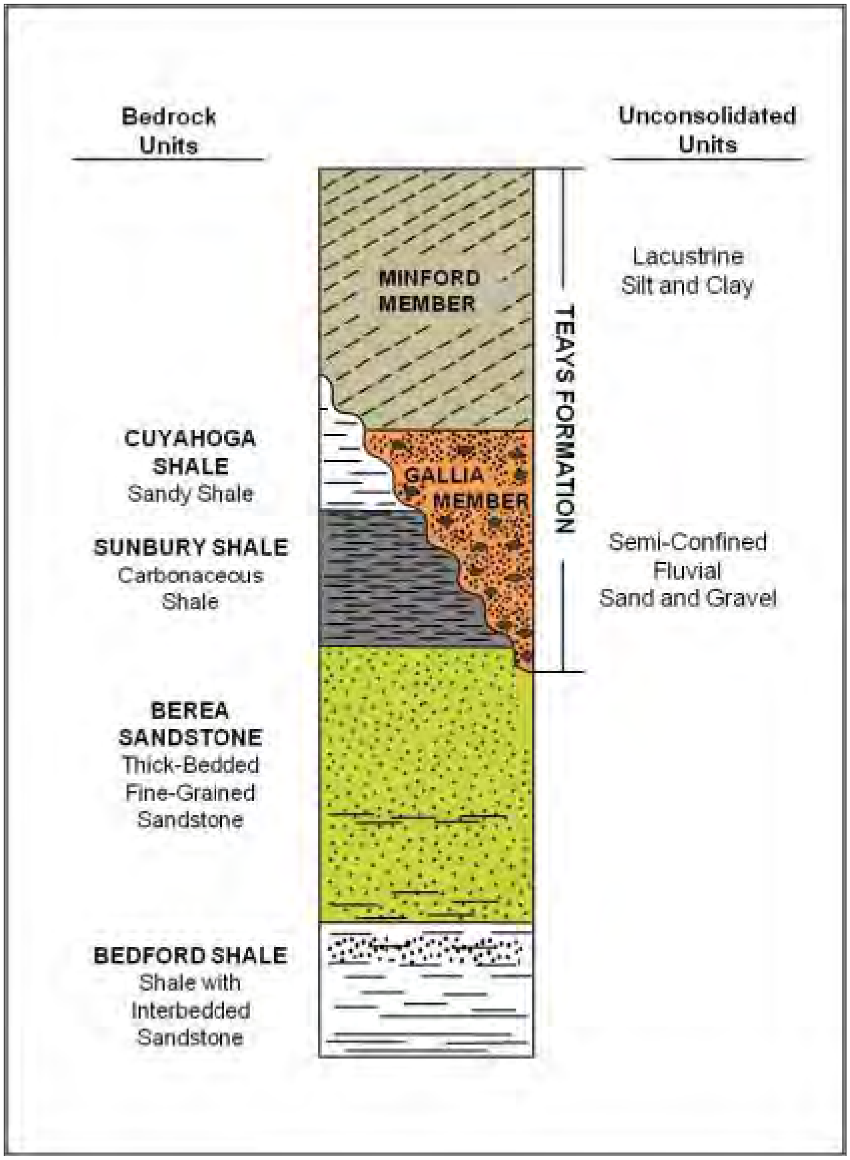


Source: DOE 2011b

Figure 3.5. Generalized Stratigraphy at PORTS

The bedrock beneath PORTS is comprised of sandstone and shale deposited in an inland sea during the late Devonian and Mississippian periods (approximately 340 million years ago) (Coogan 1996). The area was subsequently uplifted and gently folded. Erosion produced the deeply dissected, knobby terrain that characterizes southern Ohio. The near-surface bedrock formations (from oldest to youngest) are the Bedford shale, Berea sandstone, Sunbury shale, and Cuyahoga shale (Upper Devonian and Mississippian strata) that dip gently to the east-southeast at approximately 30 ft/mile. No known geologic faults are located in the immediate area. Two distinct joint sets (fractures) are present in outcrops of thin (2 to 8 in. thick) sandstone laminations in the Cuyahoga Formation and the lower Berea/upper Bedford Formations.

The Bedford shale is the lowest stratigraphic unit that has been encountered during environmental investigation activities at PORTS. The Bedford shale, continuous beneath PORTS, consists of thinly bedded shale with thin interbeds and laminations of hard, gray, fine-grained sandstone and siltstone. The typical depth to the top of this formation at PORTS is 70 to 100 ft bgs. It averages 100 ft in thickness and outcrops are present in deeply incised streams and valleys within the DOE reservation.

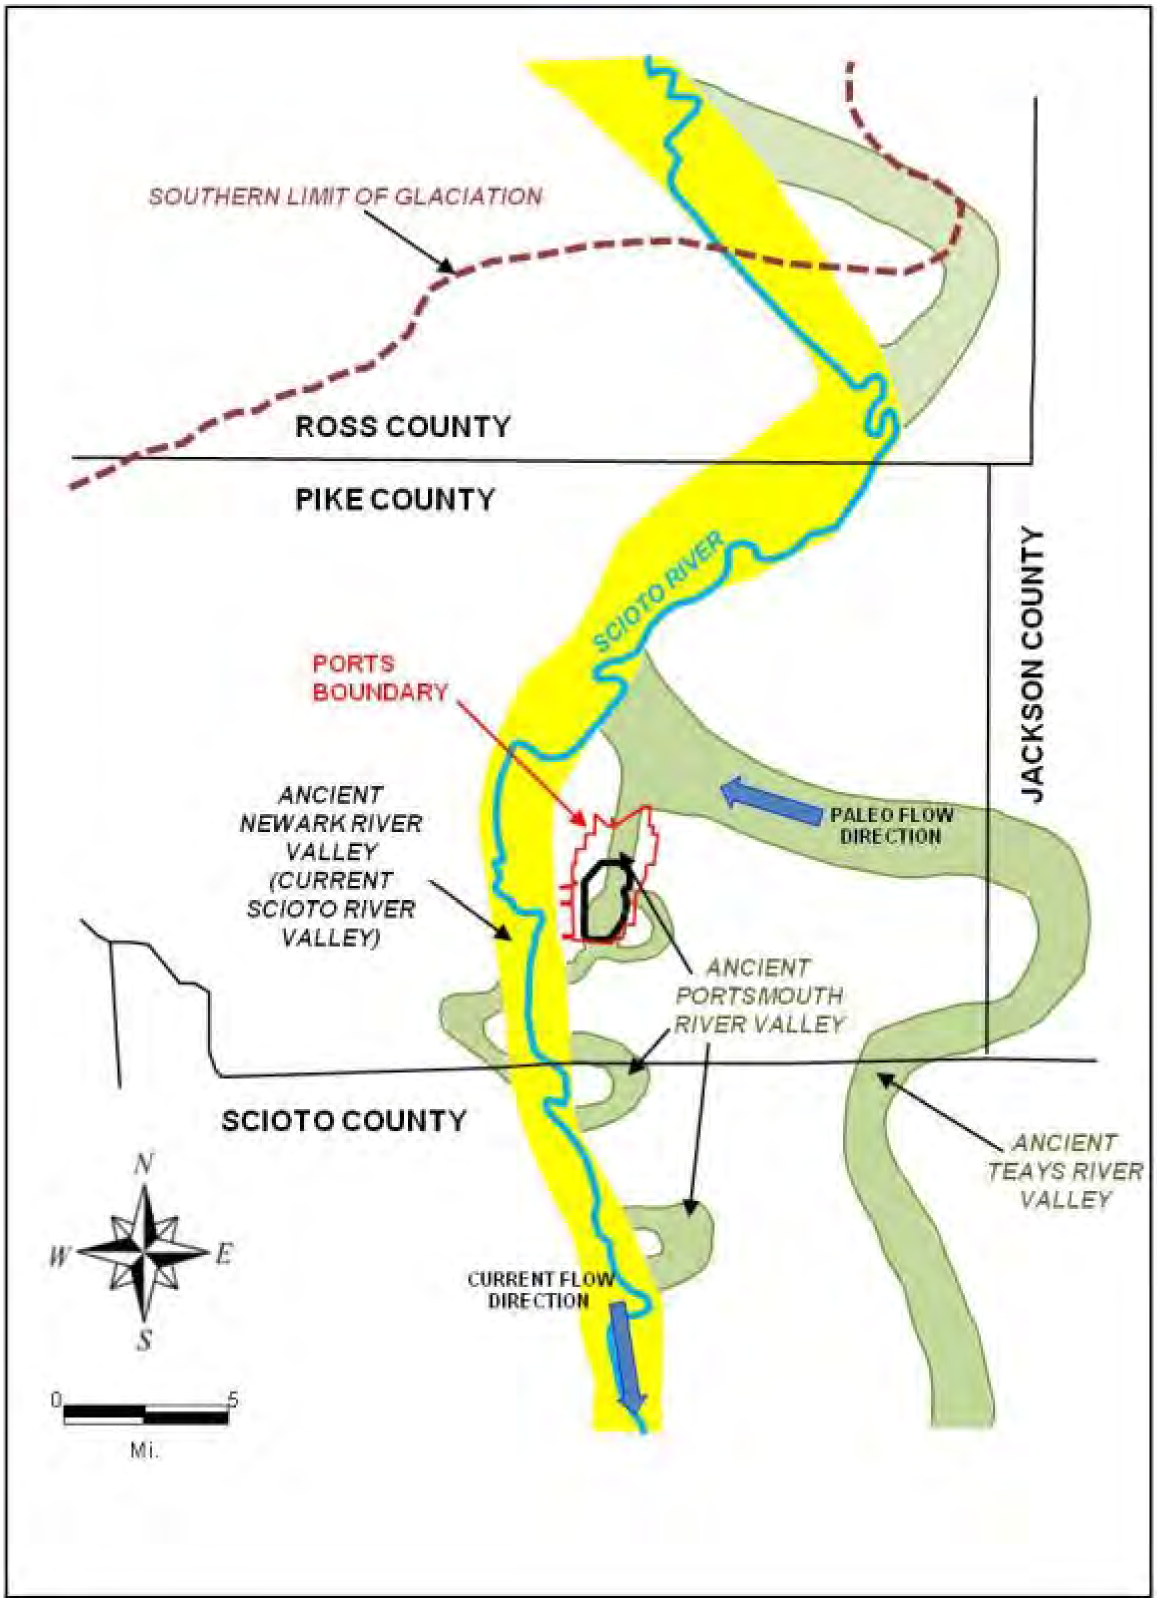
The Berea sandstone is composed of a light gray, hard, thickly bedded, fine-grained sandstone with thin shale laminations. The upper 10 to 15 ft of this formation consists of a massive sandstone bed with few joints or shale laminae. This formation is continuous beneath the industrial portion of PORTS, underlying the Sunbury shale on the eastern portion of PORTS and the unconsolidated Minford and Gallia members (Teays Formation) on the western portion of PORTS. The Berea sandstone averages 35 ft thick, and the lower 10 ft have numerous interlayered shale laminations similar to those in the underlying Bedford shale. This gradational contact does not allow for precise determination of the thickness of the Berea sandstone. Regionally, the formation contains naturally occurring hydrocarbons (petroleum) in quantities sufficient for commercial production.

The Sunbury shale is a competent, black, very carbonaceous shale that averages about 15 to 20 ft in thickness. It is typically the uppermost bedrock unit beneath PORTS, but thins westward as a result of erosion by the ancient Portsmouth River. The Sunbury shale is absent under the western half of the reservation. It is also absent in the drainage of Little Beaver Creek downstream from the X-611A Old Lime Sludge Lagoons and the southern portion of Big Run Creek, where it has been removed by erosion. The Sunbury shale underlies the unconsolidated Gallia of the Teays Formation beneath the industrialized eastern portion of PORTS and underlies the Cuyahoga shale outside of the Portsmouth River Valley.

The Cuyahoga shale, the youngest and uppermost bedrock formation in the geographic area, forms the hills surrounding PORTS. It is a moderately hard, thinly laminated shale that regionally reaches a thickness of approximately 160 ft and has numerous interbedded sandstone and siltstone laminations. The Cuyahoga Formation was deposited in an offshore, quiet water environment, perhaps on the distal margin of a delta. Most of the sandstone layers within the Cuyahoga are very thin (less than 3 in. thick), but occasionally a thicker layer (1 to 5 ft thick) is encountered in the region. The Cuyahoga shale is not found beneath the industrial portion of PORTS.

Prior to glaciation, the major drainage system in southern Ohio was the Teays River System. The river flowed northwest and passed about 3 miles north of PORTS. Glaciation occurring 25,000 to 2 million years ago changed the flow directions of streams, caused lakes to form, and filled in valleys with lake and river sediments.

The Portsmouth River, a north-flowing tributary of the Teays, flowed across the area that is now occupied by PORTS (Figure 3.6). The Portsmouth River eroded a valley into the bedrock. The Sunbury was eroded into a wedge that diminishes to the west and exposed the Berea bedrock on the western third of the facility. As the Portsmouth River meandered across the valley, silt, sand, and gravel were deposited. These unconsolidated fluvial deposits form the Gallia Member (Gallia) of the Teays Formation. The Gallia averages 3 to 4 ft in thickness across PORTS and is characterized as reddish-brown, clayey, medium-to-coarse sand and gravel (sand and gravel are typically poorly sorted). Channel migration and variation in depositional environments resulted in the variable thickness and hydraulic properties of the Gallia. The areas of thickest accumulation of Gallia sediments (exceeding 10 ft thick in some places) may represent the former channel location. They include areas under the southern end of the X-330 Process Building and near the X-701B Holding Pond. Gallia deposits beneath PORTS (found at a depth of approximately 25 ft bgs) are generally absent above an elevation of 650 ft AMSL. This



Source: DOE 1998a

Figure 3.6. Location of Ancestral River Systems in Relation to PORTS

happened because the valley walls of the ancient Portsmouth River formed a natural barrier for deposition of Gallia channel deposits.

Approximately 1 million years ago, an advancing glacier north of the plant blocked the northwestward flow of the Teays River. A glacial lake, Lake Tight, filled the valleys of the Teays River and its tributary, the Portsmouth River. The Minford member (Minford) of the Teays Formation, consisting of lacustrine silts and clays, accumulated in the lake. The Minford, which represents the uppermost stratigraphic unit beneath PORTS, consists of two units with a gradational contact. The upper unit is predominantly silty clay with some very fine-grained sand, and the lower silt unit is composed of clayey silt and very fine to fine-grained sand. Both units are continuous beneath the industrialized plant. The lower unit is indicative of shallow lake levels or over-bank deposits that grade into the upper unit of laminated silty clays, which were deposited as Lake Tight increased in size and depth. The Minford averages 20 to 40 ft in thickness with the upper unit averaging 16 ft in thickness. Eventually, Lake Tight overflowed its banks and initiated the high-volume and high-energy lower elevation drainage paths that bypassed the area of PORTS as they flowed south in the vicinity of the present-day Scioto River.

The unconsolidated Gallia and Minford members of the Teays Formation beneath PORTS are not continuous with the unconsolidated deposits in the Scioto River Valley to the west. A bedrock ridge forms a western valley wall that separates the two groups of unconsolidated deposits.

The PORTS Facility is located in the Appalachian Plateau structural province. This structural province is bounded to the west by the Cincinnati Arch structural province and to the east by the fold-and-thrust belt of the Appalachian Mountains.

Geologic studies conducted to determine the potential seismic hazard for PORTS have determined that only one fault is located within 25 miles of the plant. This fault lies approximately 18 miles to the west of the facility. No seismicity has been recorded on this fault, and no seismic events have occurred within 25 miles of PORTS during the historic period (past 100 years). Based on data from the Ohio Department of Natural Resources (ODNR), 17 earthquakes occurred within 50 miles of the plant between January 1900 and October 2011, and only a few of those were likely felt in the vicinity of PORTS (ODNR 2011a). The largest event occurred on May 17, 1901, with an epicenter approximately 20 miles from the plant and an estimated magnitude of 4.3. Since 1978, two Ohio earthquakes within 50 miles of the plant occurred with a magnitude greater than 3.0. Also since 1978, three Kentucky earthquakes within 50 miles of the plant occurred with a magnitude greater than 3.0 (Hansen 2007). It should be noted that all of the earthquakes in the area since 1978 were less than magnitude 3.6. On August 23, 2011, an earthquake with a magnitude of 5.8 occurred in east-central Virginia (approximately 285 miles from PORTS) and was felt throughout Ohio.

The Kentucky River Fault Zone and the Lexington Fault System (formerly the Bryant Station-Hickman Creek Fault) are located farther away from the plant, the latter fault being approximately 60 miles southwest. These faults bound the southern part of a north-northeast trending area of seismicity in central and eastern Ohio. Soil testing for the Gaseous Centrifuge Enrichment Plant indicated that the potential for earthquake-induced soil liquefaction at PORTS is relatively low (Law Engineering 1978). The potential for soil-structure interaction (ground motion magnification) is also slight.

3.5 SOIL

According to the soil survey of Pike County, 22 soil types occur within the PORTS property boundary. The predominant soil type at the plant is Omulga Silt Loam (U.S. Department of Agriculture [USDA] 1990). Most of the area within the active portion of PORTS is classified as Urbanland-Omulga complex with a 0 to 6 percent slope, which consists of urban land and a deep, nearly level, gently sloping, moderately well-drained Omulga soil in preglacial valleys. The urban land is covered by roads, parking lots, buildings, and railroads, making identification of the soil series difficult. The soil in these areas is so obscured or disturbed that assignment of specific soil series is not feasible. Other dominant soil types found in the upland areas surrounding the industrial complex include the Rarden, Coolville, Latham, and Wharton series.

The Omulga series is characterized as deep, nearly level, moderately drained soils formed in loess and alluvium in preglacial valleys (USDA 1990). The surface layer of Omulga Silt Loam is dark grayish-brown, friable, and approximately 10 in. thick. The subsoil is approximately 54 in. thick and is composed of three portions: (1) a yellow-brown, friable silt loam, (2) a fragipan (brittle, compacted subsurface soil) of yellow-brown, mottled, firm, and brittle silty clay loam, and (3) a yellow-brown, mottled, friable silt loam approximately 20 in. thick. Generally, the root zone is restricted to the zone above the fragipan and contains none of the urban land soils. Well developed soil horizons may not be present in all areas inside Perimeter Road because of cut and fill operations related to construction.

The remaining soil series (Rarden, Coolville, Latham, and Wharton) are similar because they are characterized as deep soils formed in shale and siltstone regolith on ridgetops and hillsides in upland areas (USDA 1990). These soils are chiefly inorganic silt and clay with some fat clay (clay of high plasticity). They have a pH ranging from 3.6 to 6.5 units whereas the Omulga soils have a slightly higher pH (4.5 to 7.3 units). The soils developed on shale regolith are characterized as having slow permeability and low available water capacity.

The soil at PORTS, whether derived from the Minford member or the Cuyahoga Formation, contains an appreciable amount of clay minerals. Clay minerals provide reaction sites for the sorption of inorganic contaminants, which then retards the migration of such contaminants in the subsurface.

3.6 HYDROGEOLOGY

The discussion of PORTS hydrogeology in this section is a summary developed from the quadrant RFI reports and annual groundwater monitoring reports mentioned at the beginning of Section 3. Data collected during the RI/FS fieldwork has been incorporated to enhance understanding of the hydrogeologic characteristics at PORTS. Further discussions of hydrogeology with regard to the candidate locations for a potential OSDC are found in Appendix D.

The groundwater flow system at PORTS includes the aquifers consisting of Berea sandstone and unconsolidated Gallia sand and gravel, along with the aquitards of Sunbury shale and unconsolidated Minford clay and silt. The basal portion of the Minford is generally grouped with the Gallia to form the uppermost and primary water-bearing unit at the facility.

Groundwater recharge and discharge areas at PORTS include both natural and man-made recharge and discharge areas. Natural recharge to the groundwater flow system comes mainly from precipitation, although land use and the presence of thick upper Minford clay deposits and the Sunbury shale effectively reduce recharge to underlying units. Discharge of groundwater to the surface occurs primarily along streams that transect the facility. Groundwater recharge and discharge areas also are influenced by man-made features, including the storm sewer system, sanitary sewer system, recirculating cooling water system, water lines, and building sumps. Groundwater flow at the plant is significantly affected by the X-700 and X-705 building basement dewatering, extraction wells in the vicinity of X-231B and X-701B, and the groundwater interceptor trenches at X-749 and X-701B. The X-700 and X-705 basement sumps remove approximately 28,000 gal of groundwater per day while the extraction wells remove a total of approximately 52,000 gal/day (DOE 2011e). The effects of man-made features on recharge and discharge would need to be accounted for during consideration of groundwater flow and transport following any D&D activities.

Groundwater flow at PORTS, at least within the Gallia, can generally be divided into four separate flow regions, or quadrants. Groundwater divides provide the basis for separation of PORTS into quadrants. The groundwater flow divides and general directions of groundwater flow for the Gallia and Berea aquifers are illustrated in Figures 3.7 and 3.8, respectively. The groundwater divides generally coincide with topographic highs along the center of the industrial complex (from south to north) and subtle topographic highs radiating outward and separating the predominant surface water features draining the facility. Locations of the flow divides may migrate because of small differences in response to seasonal changes in precipitation and groundwater recharge. In general, groundwater gradients are flatter in the upland areas in the center of the industrial complex and become steeper as groundwater approaches the streams or creeks. Vertical movement of groundwater between the Gallia and Berea is, in general, downward in upland areas of recharge and upward in areas of discharge near streams.

Groundwater flow in specific quadrants and the primary controls on groundwater flow are discussed in the following paragraphs.

The direction of groundwater flow in Quadrant I, the southern portion of the facility, is controlled by the presence of surface drainages (Big Run Creek and the Southwest Drainage Ditch), the storm sewer system, and bedrock topography. In general, groundwater in the Gallia flows from north to south, discharging into either Big Run Creek or the Southwest Drainage Ditch. In the south-central portion of the plant, groundwater in the Gallia flows primarily to the southeast toward the X-230 Holding Pond. The hydraulic gradient is very low because of the flat valley floor; the presence of thicker, more permeable Gallia deposits; and proximity to the east-west groundwater divide that runs through the facility. Storm drains have been observed to affect the local flow system at X-231B. The vertical hydraulic gradient from the Gallia to the Berea is steep, with an average difference of 8 to 10 ft near X-231B. The vertical hydraulic gradient between the Gallia and Berea decreases to the west as the Sunbury shale thins.

The flow system near X-749 exhibits a minor north-south-oriented divide in the Gallia. This divide runs near the western boundary of the landfill. Groundwater flows away from this divide to the east toward Big Run Creek and to the west toward the Southwest Drainage Ditch. Groundwater gradients are steep along Big Run Creek, which is attributed to the presence of sediment with low hydraulic conductivity and the rapid drop in elevation toward the creek. In this area, groundwater flow directions in the Berea are similar to the directions observed in the Gallia, but the north-south-oriented groundwater divide through Quadrant I is not present in the Berea.

Groundwater flow in Quadrant II, in the eastern flow region, is influenced by factors such as Little Beaver Creek, holding ponds and drainage ditches, building sumps, Minford clay thickness, and the presence and absence of the Sunbury shale. Little Beaver Creek is the local surface water discharge point for shallow groundwater flow in Quadrant II. Much of the groundwater in the Minford and Gallia along the eastern portion of PORTS migrates toward the creek. The storm sewer system in the area is typically completed in the Minford. The impact of this system as well as the sanitary sewer system on local groundwater flow in Quadrant II appears to be limited.

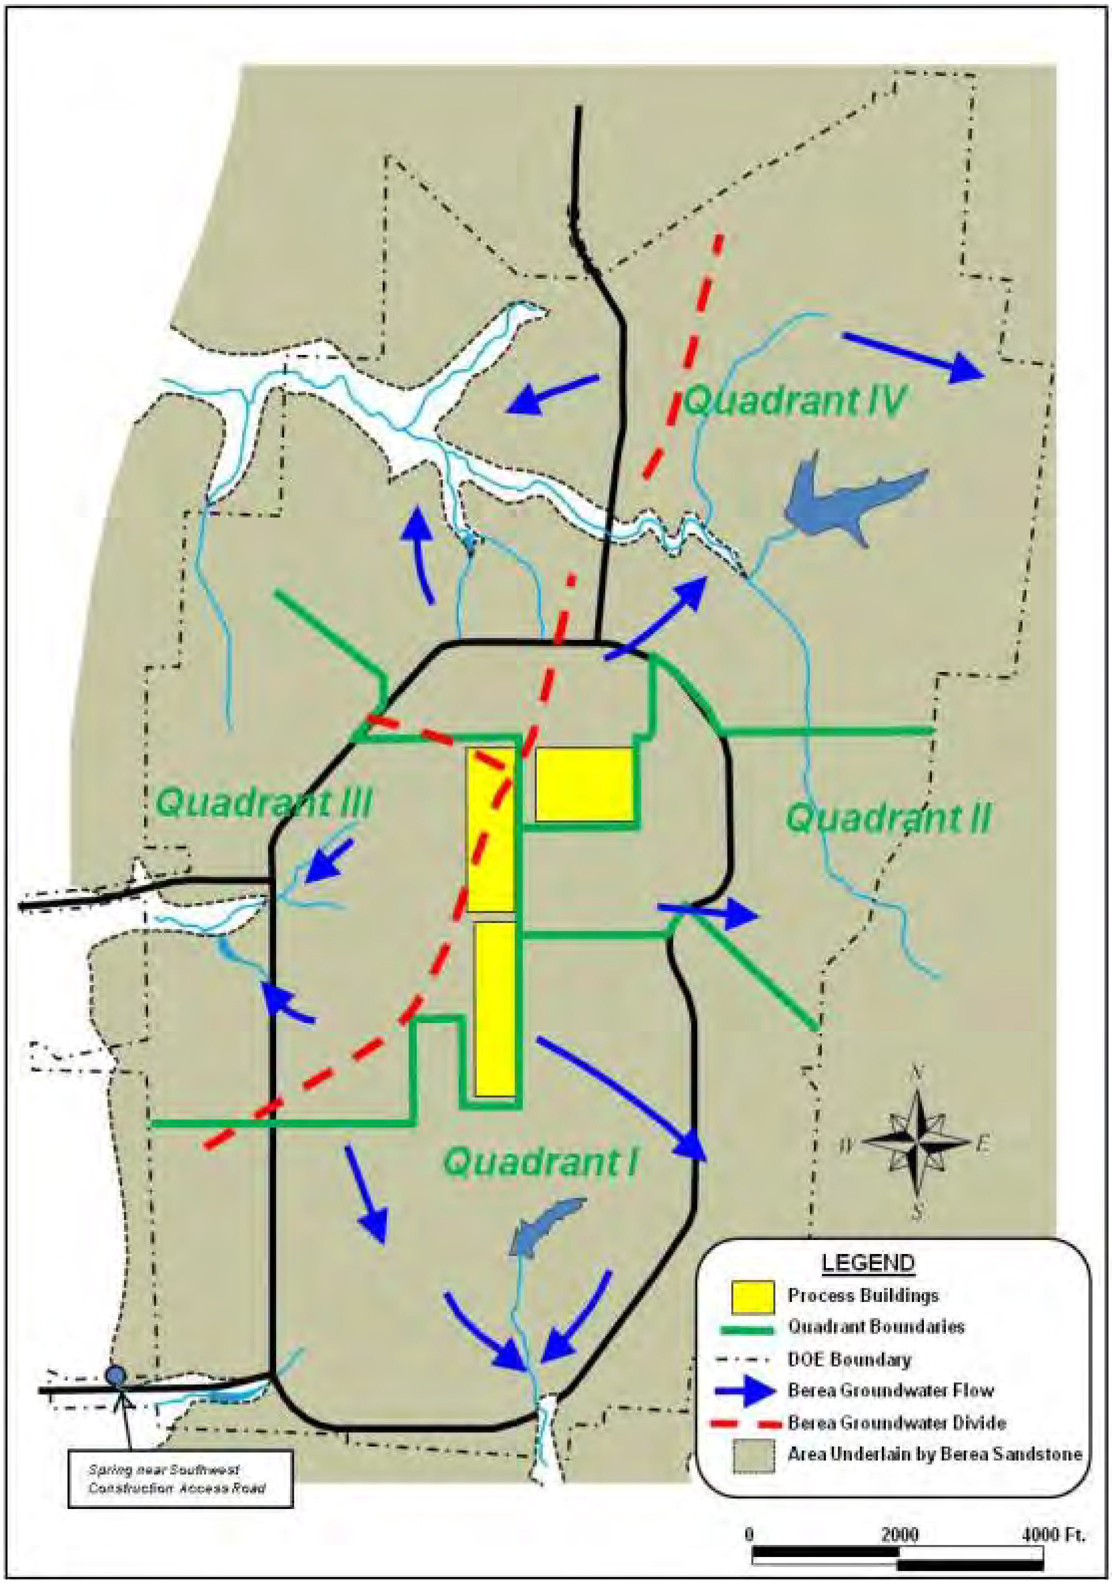
Figure 3.7. Generalized Groundwater Divides and Flow Directions for the Gallia Member at PORTS



Source: Modified from DOE 2011b

Figure 3.8. Generalized Groundwater Divides and Flow Directions for the Berea Sandstone at PORTS

Groundwater flow directions in both the Minford and Gallia are affected by the X-230J7 Holding Pond and the East Drainage Ditch. Both the holding pond and drainage ditch were excavated to bedrock, causing seepage faces to develop where the water table intersects the land surface along the side walls in both the Minford and Gallia. As a result, groundwater converges toward these local discharge areas.

In Quadrant II, groundwater flow in the Berea is primarily east to northeast. In most areas, the hydraulic gradient also is downward from the Gallia to the Berea. Vertical hydraulic gradients between the Gallia and Berea are greatest where the Sunbury is a thick, competent shale. Flow through the Sunbury is assumed to be essentially vertical. Near the X-705/X-700 buildings, where the Sunbury is thin or absent, vertical gradients indicate possible upward flow from the Berea to the Gallia. However, sumps located in the basement of the X-705 building have a significant effect on groundwater flow because they create a cone of depression centered around the active sumps.

Buildings, paved areas, and thick upper Minford clay and Sunbury shale deposits effectively reduce recharge to underlying units throughout the PORTS industrial facility. West of X-701B, recharge to the Minford and Gallia is reduced because a large portion of the land is paved or covered by buildings.

Groundwater flow in Quadrant III, the western flow region, is primarily influenced by the X-2230N Holding Pond and the West Drainage Ditch, which is the local surface water receptor for groundwater in the quadrant. As a result, much of the area groundwater in the Minford and Gallia migrates to the west and eventually discharges to the upper tributaries of the ditch. The West Drainage Ditch is deeply incised into bedrock, especially west of Perimeter Road. Seepage faces develop where the water table intersects the land surface along the side walls of the ditches in both the Minford and Gallia. Storm drains in the area are constructed in the Minford and provide only a limited effect on local groundwater flow.

Although groundwater flow in the Berea is northwest to southeast, along the west portion of Quadrant III, the direction of flow in the Berea has been altered by the West Drainage Ditch and erosion of the Berea in the Scioto River Valley to the west. In this area, groundwater flow is primarily to the west. The thinning and absence of Sunbury shale along the western portion of the plant, including in much of Quadrant III, increase the communication between the Gallia and the Berea. In most areas, the flow is downward into the Berea.

Groundwater flow in Quadrant IV, in the northern portion of the facility, is strongly controlled by Little Beaver Creek, the North Drainage Ditch, and to a lesser extent, the Northeast Drainage Ditch. In the south and southeastern portions of Quadrant IV, groundwater flow in the Gallia is strongly controlled by an east-west groundwater divide that roughly coincides with the quadrant boundary. This divide is near a bedrock high in the Cuyahoga shale.

Groundwater flow directions for the Berea in Quadrant IV approximately parallel the flow directions in the Gallia, with flow primarily to the east and north toward Little Beaver Creek and to portions of the North Drainage Ditch. Because the Berea underlies the Sunbury shale, the groundwater flow in the Berea is unaffected by the bedrock high of the Cuyahoga shale near X-633. Vertical hydraulic gradients from the Gallia to the Berea are steepest near the bedrock high in the eastern portion of Quadrant IV (0.64 to 0.76 ft/ft) and in the northwestern portion of Quadrant IV near the X-734 landfill (0.41 to 0.90 ft/ft). In the far northwestern portion of Quadrant IV, where the Berea is overlain by the Sunbury and Cuyahoga Formations, the groundwater flow direction is eastward in the direction of stratigraphic dip. Upward gradients are sometimes observed where the Sunbury shale is absent, along the southern portion of Quadrant IV near the Quadrant III/IV boundary.

The plant-wide median depth to the Gallia potentiometric surface was approximately 15 ft in 2010 (the Gallia, which behaves as a semi-confined aquifer, is found at a depth of 25 to 30 ft across the industrial portion of the plant). The water table within the Minford generally lies 10 to 15 ft bgs. Many factors can affect water table depth at a particular location, including seasonal variations from increased or decreased precipitation, surface coverings such as buildings and parking lots, topography at the location, land use, thickness of the upper clay portion of the Minford member, presence of storm drains, and operation of groundwater remediation processes (phytoremediation, extraction wells, sumps, and French drains). Based on water levels reported in the 2010 groundwater monitoring report (DOE 2011b), the water table in the Minford is usually slightly higher than the potentiometric level of the Gallia aquifer.

Groundwater is a supply source for domestic, municipal, and industrial water uses in the vicinity of PORTS. Most municipal and industrial water supplies in Pike County are developed from unconsolidated sand and gravel along the Scioto River valley. No public groundwater supply wells are located near PORTS. The village of Piketon’s water supply wells are located in the Scioto River alluvium approximately 4 miles northwest of PORTS. The PORTS water supply comes from three well fields located near the Scioto River to the east of the plant, where they draw groundwater from the Scioto River alluvium. Groundwater directly beneath PORTS is not used as a domestic, municipal, or industrial water supply. There are no source water protection areas at PORTS. Beneath the facility, the groundwater yield is often too low, because of low aquifer transmissivity, to support municipal or industrial water supplies. Domestic water supplies are obtained from unconsolidated deposits in the preglacial buried valley aquifer, major tributaries of the Scioto River, or fractured bedrock encountered during drilling. Based on a previous study, domestic wells in the immediate vicinity of the PORTS property obtain groundwater from the Berea sandstone (BJC 2003a). However, an examination of drillers logs indicate several wells obtain groundwater from fractured shale or other shallower geologic units (unconsolidated sand and gravel).

Table 3.1 provides a summary of the private groundwater wells near PORTS. This summary is based on ODNR records (ODNR 2011b). The locations of these wells are shown in Figure 3.9. As shown on Figure 3.9, many of the residential wells on the west side of PORTS are located in the alluvium of the Scioto River.

Note: “Grit” appears to be equivalent to Berea sandstone (often reported beneath a black shale); while drillers’ logs show Well 112503 in shale, regional stratigraphic relationships suggest it is open to the Berea.

ODNR = Ohio Department of Natural Resources

Four creeks, or drainage channels, drain the facility. Little Beaver Creek drains the eastern and northern portion, Big Run Creek and the Southwest Drainage Ditch drain the southeastern and southwestern portions, and the West Drainage Ditch drains the western portion. The four creeks and drainage ditches dissect the unconsolidated Minford and Gallia members, bedrock-forming Sunbury shale (where present), and Berea sandstone, resulting in the discharge of groundwater to them. Groundwater flow beneath PORTS is generally toward one of these discharge locations, and groundwater divides form between the discharge locations along areas of highest groundwater elevation.

The hydraulic properties of the hydrogeologic units have been defined during previous investigations at the facility. Groundwater flow at the plant has been well defined by single-well aquifer tests of the Berea sandstone and Gallia sand and gravel. The average hydraulic conductivity for the Minford clay is 2.3×10^{-4} ft/day, and the average hydraulic conductivity for the Minford silt is 4.3×10^{-3} ft/day. These values are based on numerous laboratory tests. The vertical hydraulic conductivities of Minford clay and Minford silt are approximately an order of magnitude lower than their horizontal hydraulic conductivities. The hydraulic conductivity determined by single-well aquifer tests of the Gallia ranges from 0.11 to 150 ft/day with a mean value of 3.4 ft/day (DOE 1996a). In 2008, an aquifer performance test was conducted near the X-740 Waste Oil Handling Facility to estimate the hydraulic characteristics of the Gallia and Berea Formations and determine the interconnectedness between these two units (DOE 2009a). That test determined the hydraulic conductivity for the Gallia to be 1.71 ft/day, which is comparable to the results from previous testing. The test also demonstrated the two aquifer units in that area are relatively interconnected.

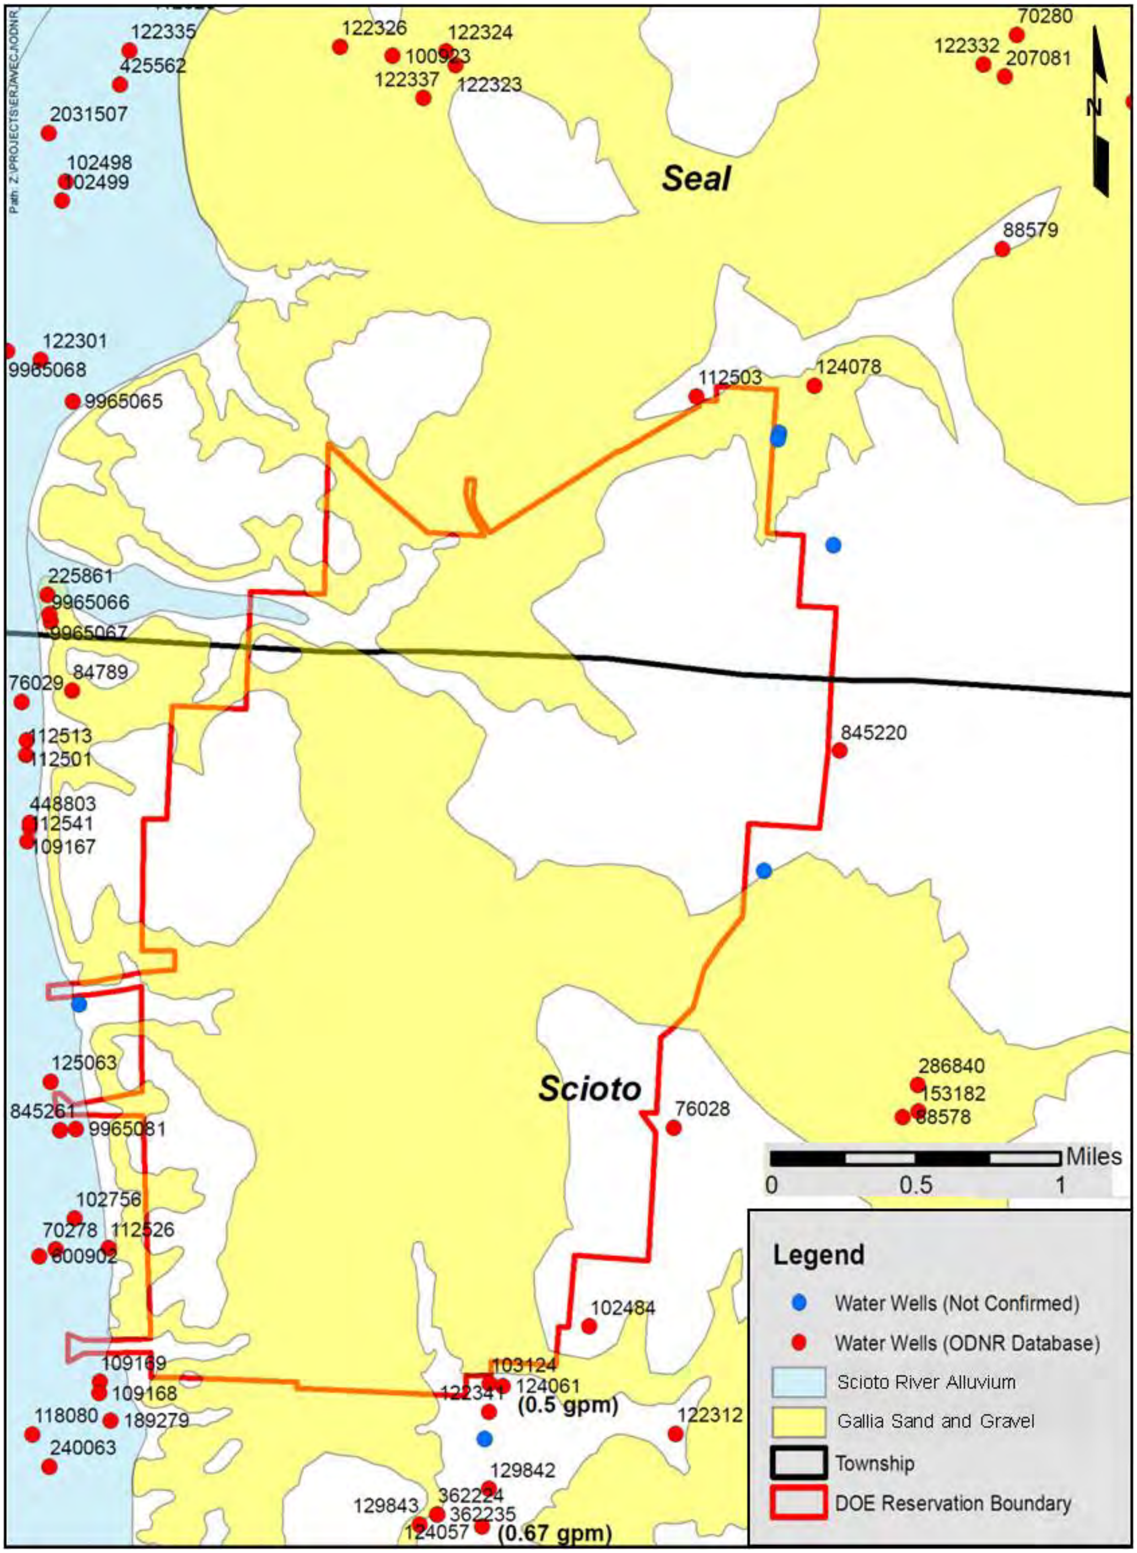

Figure 3.9. Off-PORTS Private Domestic Water Wells at PORTS

The estimated hydraulic conductivity of the Sunbury shale, based on numerical groundwater modeling, ranges from 1.6×10^{-4} to 9.6×10^{-4} ft/day (DOE 2011b). The vertical hydraulic conductivity of the Sunbury shale is assumed to be an order of magnitude lower than its horizontal hydraulic conductivity (measured values of vertical hydraulic conductivity average approximately 1.3×10^{-5} ft/day). The hydraulic conductivity determined by single-well aquifer tests of the Berea sandstone ranges from 4.5×10^{-3} to 15.0 ft/day with a mean value of 0.16 ft/day. The higher hydraulic conductivity tends to occur in areas where the Sunbury shale is absent. In the 2008 aquifer test near X-740, the Berea Formation exhibited a hydraulic conductivity of 0.56 ft/day (DOE 2009a).

The groundwater monitoring report for calendar year 2010 (DOE 2011b) determined groundwater flow velocities in the Gallia and Berea aquifers. The semiannual hydraulic gradients and linear velocities for these water-bearing units in various monitoring areas at PORTS are summarized in Table 3.2.

Table 3.2. Groundwater Linear Velocity Ranges Calculated for PORTS Monitoring Areas Using Calendar Year 2010 Data

Monitoring Area	Gallia Velocity Ranges[a] (ft/d)	Berea Velocity Ranges[a] (ft/d)
X-749/X-120/PKL	0.08-0.6	0.1-0.3
Quadrant I/X-749A	0.2-1.2	0.1
Quadrant II	0.3-0.4	None[b]
X-701B	0.1	0.2[c]
X-633/X-533	0.03-0.06	None[b]
X-616	1.5-2.4	0.8-1.4
X-740	0.2	0.2-0.3
X-611A	None[b]	0.4
X-735	1.7-6.9	0.03
X-734	0.1	0.02

[a] Some of the monitoring areas are divided into more than one zone. The ranges reflect the calculated extremes for the zones over the two monitoring periods (first or third quarters 2010).

[b] Velocity is not provided for the Berea aquifer at Quadrant II and X-633/X-533 because insufficient data are available for the Berea in these areas. Velocity is not provided for the Gallia aquifer at X-611A because the Gallia is expected to be absent in this area, and Gallia wells are installed only on the western and southern edges of the area.

[c] Not determined in calendar year 2010; value reported is from calendar year 2008 data.

PKL = Peter Kiewit Landfill

Several areas of groundwater contamination have been identified at PORTS. The main contaminants are VOCs (TCE) and radionuclides (uranium, technetium-99). Defined groundwater contaminant plumes consisting primarily of TCE are found at five of the groundwater monitoring areas (Figure 3.10). These areas include the X-749 Contaminated Materials Disposal Facility/X-120 Old Training Facility/Peter Kiewit Landfill, Quadrant I Groundwater Investigative Area, Quadrant II Groundwater Investigative Area, X-701B Holding Pond, and X-740 Waste Oil Handling Facility. The TCE plume originating in the X-749/X-120/Peter Kiewit Landfill area had migrated off PORTS, at contamination levels less than the drinking water standard, until additional remedial actions were implemented to halt further off-PORTS migration. Due to underlying geology, other PORTS contaminant plumes will discharge to surface water rather than migrate off PORTS as a groundwater contaminant.

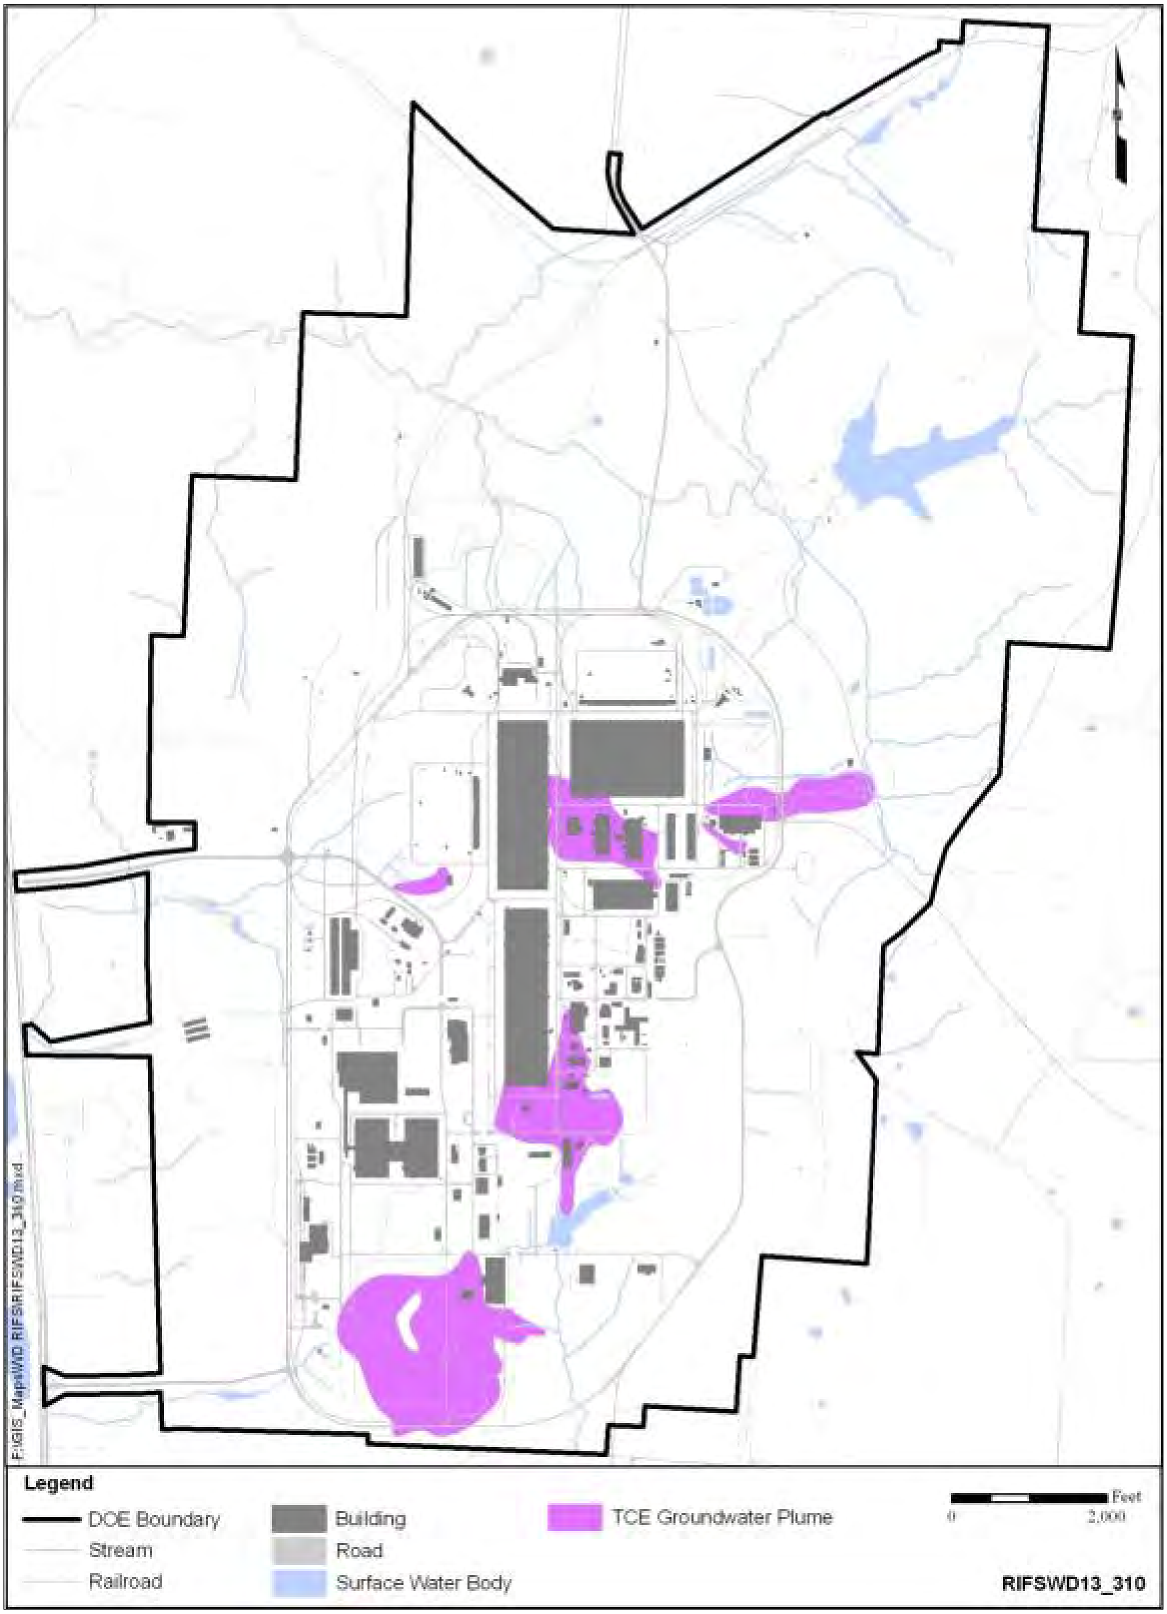

Figure 3.10. Groundwater Contamination (TCE) in the Gallia Member at PORTS

3.7 DEMOGRAPHY AND LAND USE

PORTS is situated on a 3,777-acre parcel of DOE-owned land in Scioto Township, Pike County, Ohio. It is located 2 miles east of the Scioto River and within the Scioto River drainage basin. PORTS is in a small valley running parallel to and approximately 130 ft above the floodplain of the Scioto River.

3.7.1 Population and Socioeconomics

The economic region of influence (ROI) for PORTS includes four counties in southern Ohio: Ross County, Scioto County, Jackson County, and Pike County (Figure 3.11). The largest city within 50 miles of PORTS is Chillicothe, Ohio, with a population of 21,901 persons, based on year 2010 census results (Ohio Department of Development [ODOD] 2011a). The city of Chillicothe in Ross County, Ohio, is located approximately 27 miles north of PORTS.

Pike County, one of the least populated counties in Ohio, has 28,709 residents with a population density of 65 people per square mile. The Pike County population is projected to increase by approximately 8.3 percent by 2020 (ODOD 2011b). Scattered rural development is typical; however, the county contains a number of small villages such as Piketon and Beaver, which lie within a few miles of the plant. The county's largest community, Waverly, is approximately 10 miles north of the plant and has a population of 4,408 residents. The nearest residential center in this area is Piketon, which is about 5 miles north of PORTS on U.S. Highway 23. Piketon has a population of 2,181 (ODOD 2011a). Several residences are located adjacent to the southern half of the eastern PORTS boundary and along Wakefield Mound Road (old U.S. 23), directly west of the plant. Residences are also present outside the DOE boundary to the northeast of PORTS.

The total labor force in Pike County was approximately 10,900 in 2008. Total average employment in the same year was 9,737. Based on these numbers, the major employment sectors were manufacturing (31.1 percent); government (18.3 percent); trade, transportation, and utilities (13.3 percent); education and health services (11.6 percent); professional and business services (7.1 percent); leisure and hospitality (6.8 percent); and construction (6.7 percent) (ODOD 2011b).

By 2009, the labor force in Pike County had increased to approximately 11,200. Of this total, approximately 9,500 people were employed and 1,700 were unemployed. In 2008, the unemployment rate had been 10.1 percent in Pike County, but it increased to 15.1 percent in 2009, which was a 33 percent increase in the unemployment rate in just 1 year (ODOD 2011b).

The average 2008 per capita personal income in Pike County was $26,163, compared to the state average of $35,889 and the national calendar year 2008 average of $40,166 (ODOD 2011c).

3.7.2 Land Use

Land use in the general vicinity of PORTS includes urban land, residential areas, private and commercial farms, light industries, and transportation corridors (highways and railroads) (NRC 2006a). In Pike County the land use is approximately 66 percent forest, 23 percent cropland, and 8 percent pasture. The remaining 3 percent is classified as urban land, open water, and bare/mines areas (ODOD 2011b). The latter classification refers to largely unvegetated areas of nonurban land, some of which may be associated with mining. Two public recreational areas are located in the vicinity of PORTS. One is Brush Creek State Forest, located 5 miles to the southwest of the plant. The other is Lake White State Park, located 6 miles north of the plant (NRC 2006a).

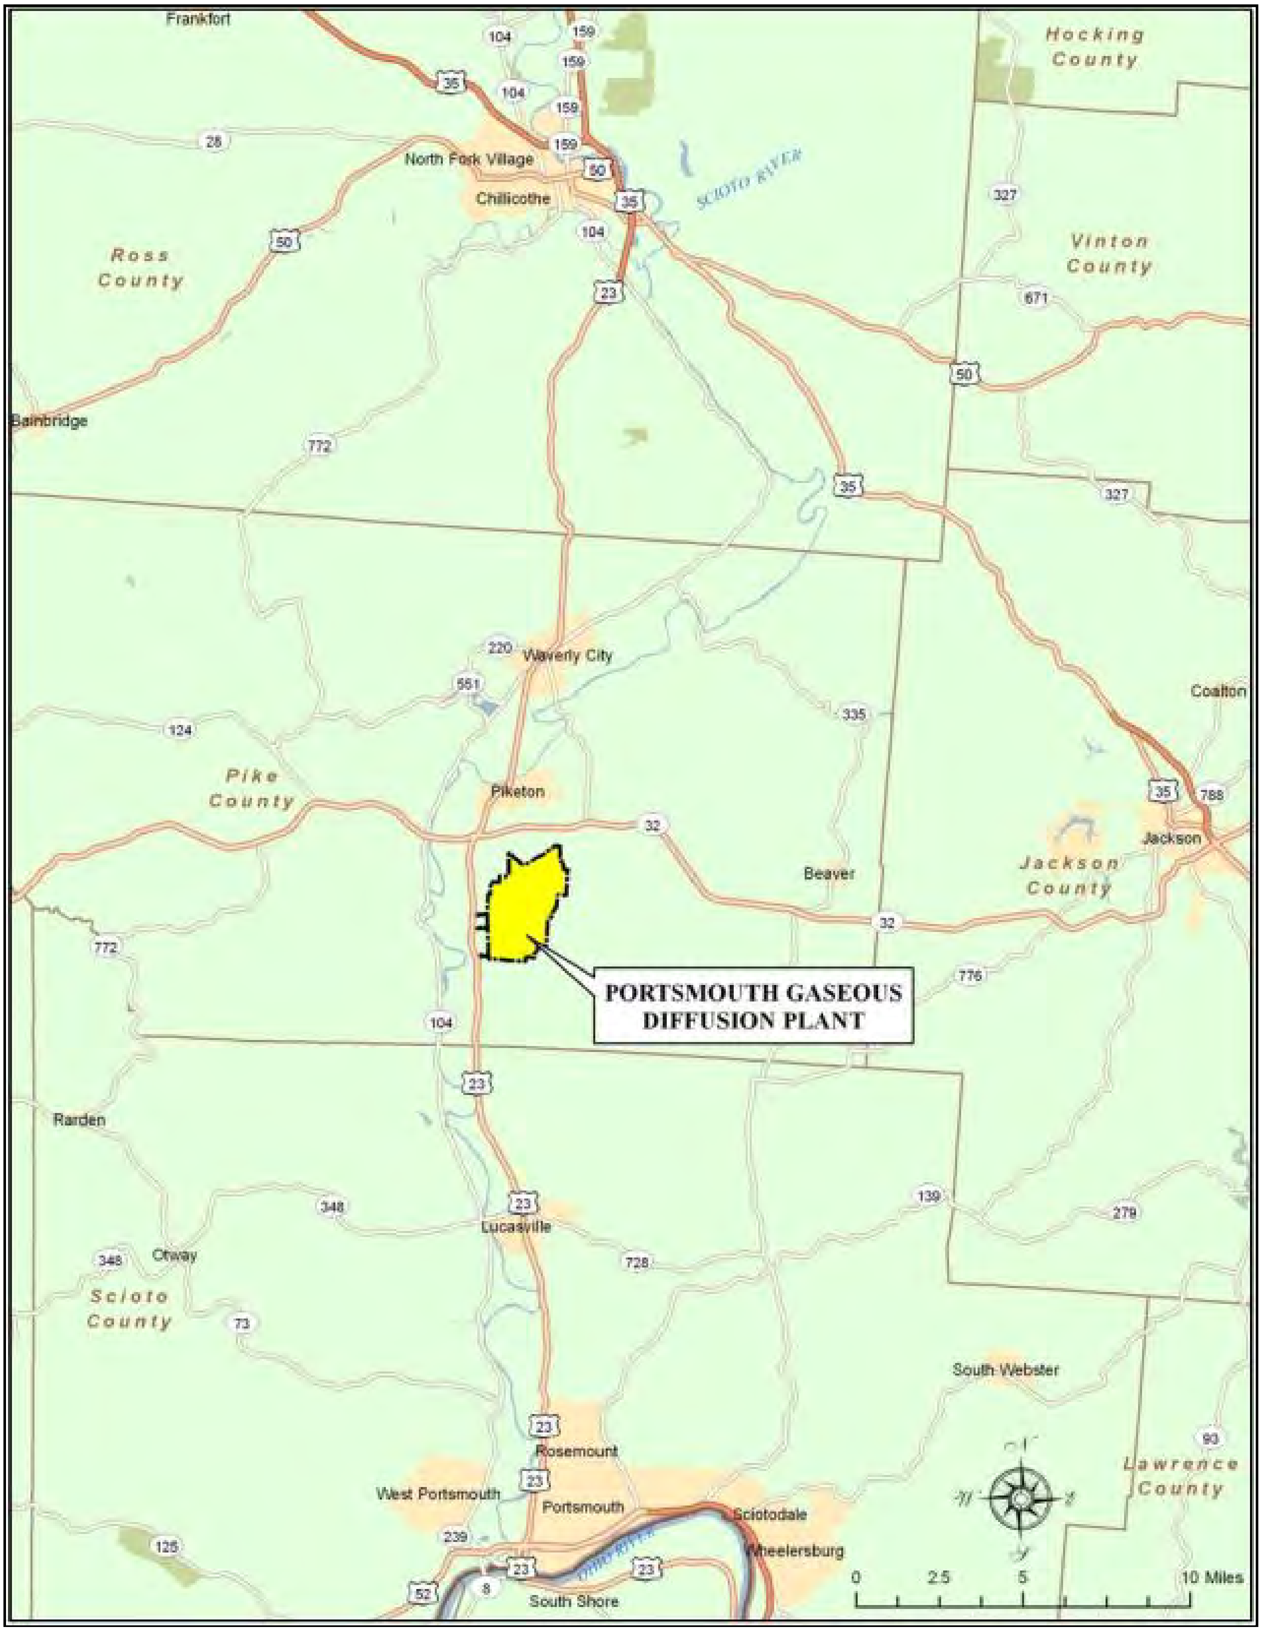

Figure 3.11. Locations of the Four ROI Counties Relative to PORTS

In the immediate area surrounding PORTS, land is used primarily for farms, pastures, forests, and rural residences. The dominant land use is farming with approximately 25,430 acres of farmland. Farmland that qualifies for protection under the Farmland Protection and Policy Act of 1981 is located primarily along the Scioto River floodplain. Marginal quality farmland is located adjacent to PORTS and on the plant. The soil survey of Pike County indicates that soils adjacent to PORTS and on the plant are of low fertility and do not qualify as prime farmland. The land surrounding PORTS has 24,400 acres of forest cover (NRC 2006a).

At PORTS, Perimeter Road surrounds a 1,300-acre centrally developed industrial use area, which includes a 750-acre controlled access area. The portion of the plant outside of Perimeter Road has approximately 2,500 acres of land that include several areas of contiguous parcels ranging in size from 1 to over 1,000 acres. Land uses in this area include a water treatment plant, holding ponds, sanitary and inert landfills, cylinder storage yards, parking areas, open fields, and forested buffer areas (NRC 2006a).

More than 400 facilities are present at PORTS. They include the three large process buildings, support buildings and structures, utilities, plant systems, holding ponds, and infrastructure. Approximately 75 percent of these facilities are included in the PORTS D&D Project. Two new facilities have been constructed over the last several years at PORTS: (1) the USEC American Centrifuge Plant built and owned by USEC pursuant to their NRC license, which will produce enriched uranium for commercial nuclear reactor fuel, and (2) the Depleted Uranium Hexafluoride (DUF_6) Conversion Facility, which was constructed by DOE to convert DUF_6 into constituents for disposal and commercial resale. In addition, a new dry air facility and a steam generation plant have recently been constructed.

Most operations at PORTS are supported by a steam plant, electrical switchyards, cooling towers, cleaning and decontamination facilities, water and wastewater treatment plants, maintenance and laboratory facilities, and office buildings. The buildings and other facilities are connected and served by an extensive network of utilities, plant systems, streets, roads, and sidewalks. Plant utilities include dry air, nitrogen, potable water, fire suppression water, cooling water, steam for heating, electric power, and a sewer system. DOE is continuing demolition of inactive, surplus facilities at PORTS. Between 2006 and 2008, DOE demolished approximately 16 inactive facilities (DOE 2010b). In 2009, DOE Headquarters continued the planning process for D&D of the PORTS gaseous diffusion buildings and facilities, which was initiated in 2007 (DOE 2011d).

Currently, DOE has two real property leases with the Southern Ohio Diversification Initiative (SODI). The first lease between DOE and SODI was signed in April 1998 for 7 acres of land on the north side of the DOE property. This tract is used as a right-of-way for a railroad spur that connects to the existing DOE north rail spur. SODI subleases a portion of this property to the Glatfelter Corporation to allow access to the rail line for a wood-grading operation. In October 2000, a second lease between DOE and SODI was signed to allow concurrent SODI access to and use of the existing north rail spur.

3.7.3 Cultural Resources

Cultural resources include any prehistoric or historic district, site, building, structure, or object resulting from, or modified by, human activity. Under federal regulations (36 *CFR* 800), federal agencies must assess the impacts their actions have on historic properties and, if appropriate, avoid, minimize, or mitigate adverse effects. Historic properties are cultural resources listed in, or eligible for listing in, the National Register of Historic Places (NRHP) because of their significance and integrity.

PORTS and its surrounding area have the potential to yield both prehistoric and historic cultural resources. Beginning in 1996 and continuing until 2012, DOE has conducted a number of cultural resource surveys. The purpose of the surveys was to identify historic properties.

3.7.3.1 Previous archaeological surveys

In September 1996 and April-May 1997, a Phase I literature review and archaeological survey were conducted at PORTS. The Phase I archaeological survey resulted in the identification of 36 previously undocumented archaeological sites within the PORTS boundary (Table 3.3). These were recorded in the Ohio Archaeological Inventory. The prehistoric sites include five isolated artifact finds and two lithic scatters. Lithic scatters consist of prehistoric stone tools and the discarded stone debris from making them. Two sites contain both prehistoric and historic temporal components represented by an isolated prehistoric artifact find/historic cemetery and a prehistoric lithic scatter/historic farmstead. Thirteen of the sites identified in the 1996-1997 surveys contain the remnants of historic-era farmsteads, seven sites are represented by historic artifact scatters or open refuse dumps, two sites are represented by isolated historic artifact finds, four sites are represented by PORTS-related structural remnants, and one site is another historic cemetery (Schweikart et al. 1997). All of these sites are located outside of Perimeter Road (DOE 2007b).

Table 3.3. Archaeological Sites Identified in the Phase I Survey within the PORTS Boundary

Site Number	Site Name	Temporally Diagnostic Artifacts/Remains	Temporal Designation	Recommended as an Historic Property[a]
33Pk184	Davis Farmstead	Architectural features; glass; ceramics; container caps	Historic	No[c]
33Pk185	South Shyville Farmstead	Architectural features; glass; ceramics; container caps; batteries; harness/strapping	Historic	No[c]
33Pk186	None	Lithic scatter	Prehistoric	No
33Pk187	Unnamed Farmstead	Architectural features	Historic	No
33Pk188	None	PORTS-related structural remnants	Historic	No
33Pk189	Mount Gilead Cemetery	Isolated artifact find (prehistoric) and 70 headstones, footstones, and other burial-related monuments	Prehistoric and historic (MC)	No[b]
33Pk190	None	PORTS-related structural remnants	Historic	No
33Pk191	None	Open refuse dump	Historic	No
33Pk192	None	Open refuse dump	Historic	No
33Pk193	Iron Wheel Farmstead	Architectural features; glass; ceramics; container caps	Historic	No[c]
33Pk194	North Shyville Farmstead	Architectural features; glass; ceramics; container caps	Historic	No[c]
33Pk195	Beaver Road Farmstead	Architectural features; glass; ceramics; container caps; harness/straps; iron pulley	Historic	No[c]
33Pk196	None	PORTS-related structural remnants	Historic	No
33Pk197	Dutch Run Farmstead	Architectural features; no artifacts	Historic	No[c]
33Pk198	None	Isolated artifact find	Prehistoric	No
33Pk199	None	Isolated artifact find	Historic	No
33Pk200	None	Historic artifact scatter	Historic	No
33Pk201	None	Isolated artifact find	Historic	No
33Pk202	None	Historic artifact scatter	Historic	No
33Pk203	Ruby Hollow Farmstead	Architectural features; glass; ceramics; container caps; metal conduit; brass button; nail; ferrous blobs	Historic	No[c]

Table 3.3. Archaeological Sites Identified in the Phase I Survey within the PORTS Boundary (Continued)

Site Number	Site Name	Temporally Diagnostic Artifacts/Remains	Temporal Designation	Recommended as an Historic Property[a]
33Pk204	None	Isolated artifact find	Prehistoric	No
33Pk205	None	Isolated artifact find	Prehistoric	No
33Pk206	Terrace Farmstead	Lithic scatter/architectural features; glass; ceramics; brick; container caps; wire; nails; sheet metal; ferrous blobs	Prehistoric and historic (MC)	No[c]
33Pk207	None	Isolated artifact find	Prehistoric	No
33Pk208	None	Isolated artifact find	Prehistoric	No
33Pk209	None	Historic artifact scatter	Historic	No
33Pk210	None	Lithic scatter	Prehistoric	No
33Pk211	Bamboo Farmstead	Architectural features; glass; ceramics; container caps; aluminum pot; metal cans; license plate	Historic	No[c]
33Pk212	Railside Farmstead	Architectural features; glass; iron pry bar	Historic	No[c]
33Pk213	Log Pen Farmstead	Architectural features; glass; container caps	Historic	No[c]
33Pk214	Holt Cemetery	Three headstones and 15 human burial depressions	Historic	No[b]
33Pk215	None	Open refuse dump	Historic	No
33Pk216	None	Open refuse dump	Historic	No
33Pk217	Stockdale Road Dairy Farmstead	Architectural features; glass; ceramics; brick; container caps; aluminum connector; hacksaw blade	Historic	No[c]
33Pk218	Cannett Road Farmstead	Architectural features; glass; ceramics; metal hinge with screws	Historic	No[c]
3Pk219	None	PORTS-related structural remnants	Historic	No

Source: DOE 2007b, Schweikart et al. 1997, Klinge 2009, Klinge and Mustain 2011, Pecora and Burks 2013

[a] As defined in 36 *CFR* 800.16.
[b] The OHPO considers the two cemeteries to be NRHP-eligible.
[c] Determinations made from Phase II surveys conducted post-1996/1997.

MC This is a multiple component archaeological site that shows evidence of both a prehistoric and historic occupation.

CFR = Code of Federal Regulations
DOE = U.S. Department of Energy
NRHP = National Register of Historic Places
OHPO = Ohio Historic Preservation Office
PORTS = Portsmouth Gaseous Diffusion Plant

Investigators recommended that 20 of the 36 sites do not meet NRHP eligibility criteria and do not qualify as historic properties. Preservation was recommended by the Ohio Historic Preservation Office (OHPO) for the two cemeteries, Mount Gilead Cemetery and Holt Cemetery, despite the fact that cemeteries are generally not eligible for nomination to the NRHP. One prehistoric lithic scatter and 13 farmsteads were recommended for further study.

Phase II archaeological test excavations at the prehistoric lithic scatter site were performed in 2003 (DOE 2011d). The results of the Phase II investigation indicated that the portions of the site on DOE property are not eligible for listing on the NRHP (the site extends beyond the DOE boundary). In 2010 and 2011, Phase II eligibility testing of the remaining farmsteads was conducted. None of the sites were found to be eligible for the NRHP.

During the planning phase of the work for the Phase II investigations of the farmsteads first identified in the 1996-1997 surveys, a number of maps and other materials were located to provide additional information on the settlement pattern of the area in the early 1900s. An examination of the materials identified farmsteads that also warranted investigation. Reconnaissance-level surveys were conducted of the farmsteads. Eleven were recommended for Phase I surveys, and of those 11, one was recommended for a Phase II survey. All the surveys concluded that none of the properties are eligible for the NRHP (Klinge 2009, Klinge and Mustain 2011, Pecora and Burks 2013, Pecora et al. 2013).

The Ohio Archaeological Inventory at the OHPO contains records on approximately 2,000 prehistoric Native American mounds in Ohio. Some of these mounds were once present on the floodplain of the Scioto River to the west of PORTS. Over the past 200 years, erosion, logging, plowing, and development have erased these mounds and many others in Ohio. However, some may remain as very low topographic rises on the landscape and are perceptible with the aid of geographic information systems (GIS) and remote sensing technology (Burks 2011).

As of 2011, no prehistoric mounds had been documented at PORTS. During May and June 2011, a study was conducted of the entire PORTS Facility using advanced technology to determine if there were prehistoric mound-like features on the plant. This study included a detailed review of the PORTS preconstruction topographic maps and the use of high-density Light Detection and Ranging (LiDAR) data. As a result, 28 topographic features (1 to 10 ft tall and up to 82 ft in diameter) were identified at PORTS. However, archaeological ground-truthing visits to each location indicated that all of these features were either naturally occurring features or a result of historic-era or recent activity at PORTS (Burks 2011).

The study concluded that PORTS contains no prehistoric mounds 1 ft tall or taller, which is the vertical size range of nearly all such documented mounds in Ohio. If smaller or more deflated mounds are present on the plant, they are not detectable using LiDAR data or visual examination for topographic features.

3.7.3.2 OSDC Study Area archaeological surveys

In late 2011, archaeological surveys were initiated of the perimeter areas of PORTS not previously surveyed. The surveys were conducted to complete the Section 110 National Historic Preservation Act (NHPA) survey efforts that were begun in 1996, 1997. The surveys included two OSDC Study Areas (Figure 3.12) under evaluation for on-Site disposal and areas that may be required for support activities. OSDC Study Area D is located in the northeast corner of PORTS and was divided into two distinct areas, Archaeological Study Area 1 and Archaeological Study Area 2. OSDC Study Area C was designated as Archaeological Study Area 3 for the purposes of the archaeological surveys. OSDC Study Area B is located inside Perimeter Road, within a previously disturbed area, and does not require additional archaeological survey. OSDC Study Area A is partially located inside Perimeter Road. The portion outside of Perimeter Road is coincident with OSDC Study Area C.

<u>*Archaeological Study Area 1*</u>

A Phase I archaeological survey was conducted of an approximately 320-acre parcel. The survey effort also included the survey of a proposed test pit location in a previously soil-disturbed area near the center of Archaeological Study Area 1. Five archaeological sites were identified during the survey in Archaeological Study Area 1: four considered prehistoric with chert flakes and one historic with glass and nails. None are considered historic properties. All were located in the far south portion of the survey area. No archaeological sites were identified in the proposed test pit location (Mustain 2013).

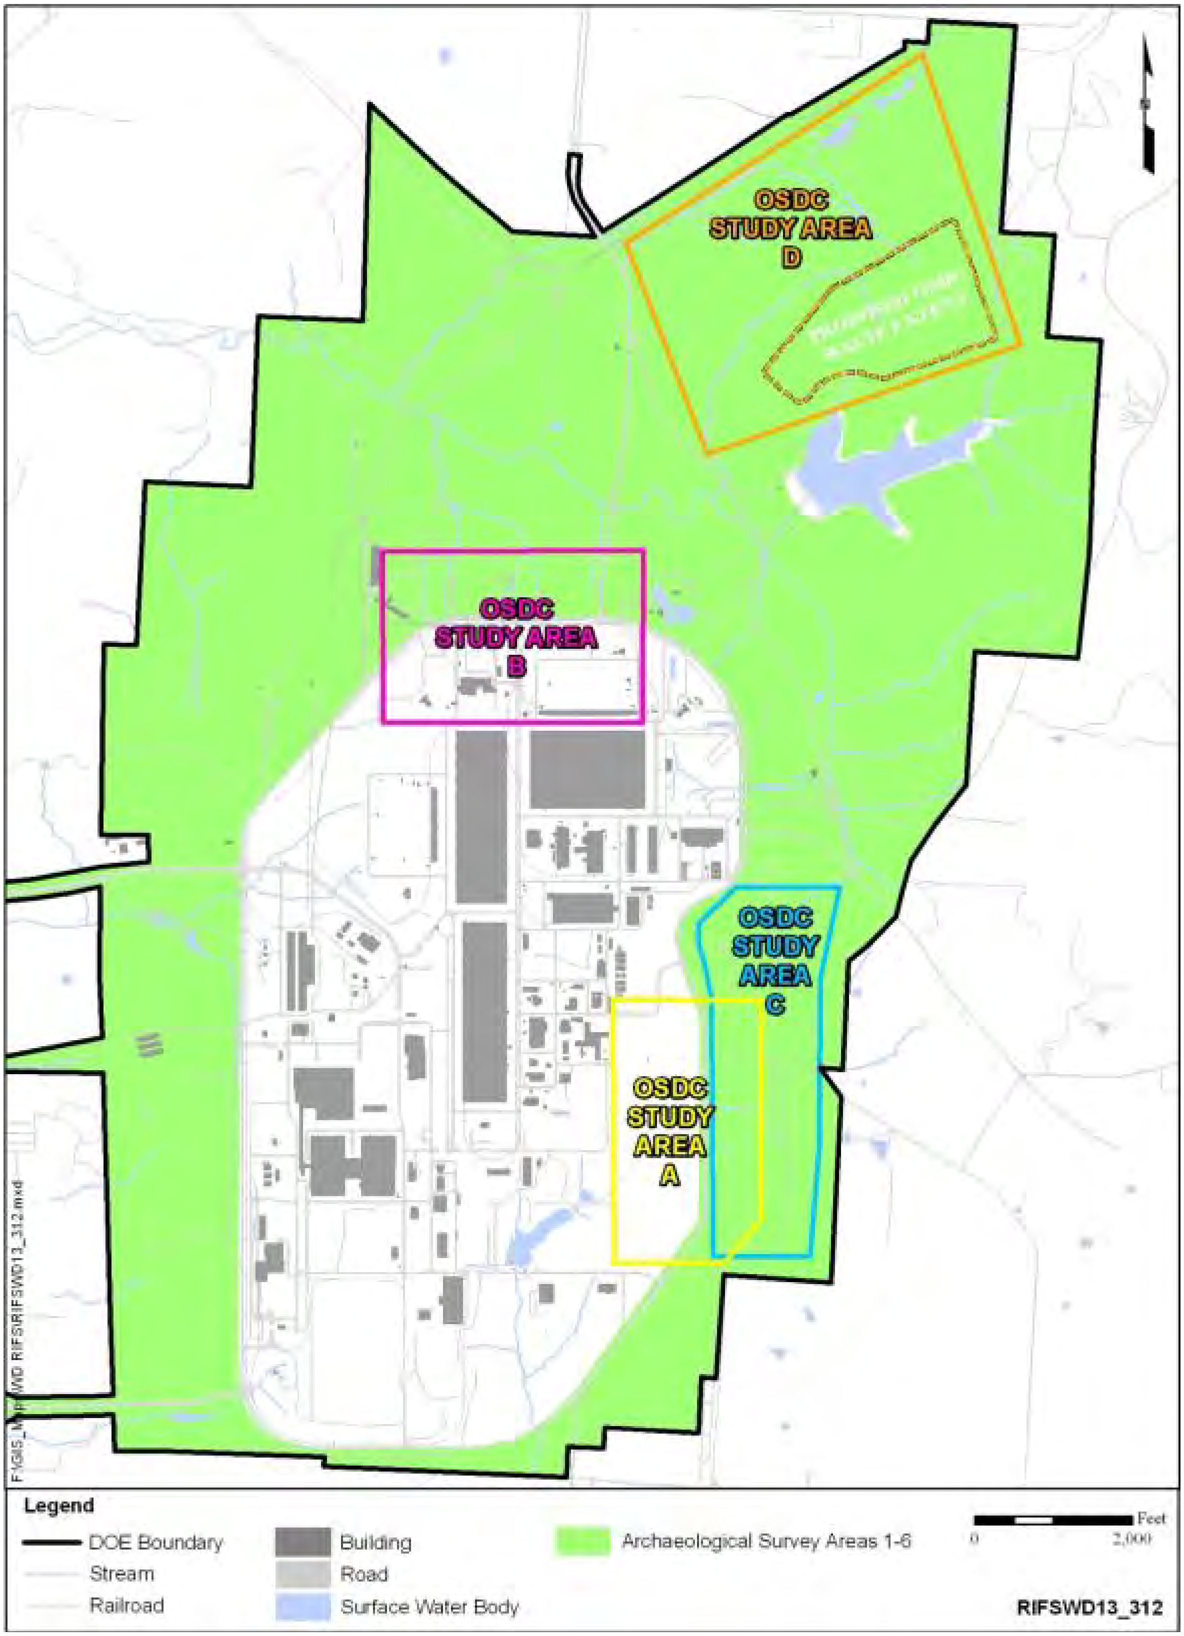

Figure 3.12. Archaeological Study Area Locations

Archaeological Study Area 2

A Phase I archaeological survey was conducted of an approximately 352-acre parcel of land in the far northeast corner of PORTS. As a result of the Phase I survey, a Phase II assessment study was recommended and performed for three sites identified within the parcel. As a result of the Phase II investigation, two sites are recommended as eligible for listing on the NRHP. The two eligible sites are prehistoric with numerous artifacts. In addition, the Holt Cemetery is found within this archaeological study area. The OHPO has recommended that the cemetery is NRHP-eligible. DOE is evaluating impacts of the proposed actions for potential adverse effects to historic properties and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

Archaeological Study Area 3

A Phase I archaeological survey was conducted of an approximately 361-acre parcel of land within PORTS, referred to as Archaeological Study Area 3, located east of Perimeter Road and the PORTS building complexes. Previous cultural resource work at PORTS identified a total of 20 recorded archaeological sites in Archaeological Study Area 3. During the 2012 survey, no additional fieldwork was performed at these previously recorded sites. Ten new archaeological sites were identified as a result of the Phase I archaeological investigations of Archaeological Study Area 3. However, none were determined eligible for the NRHP, and no further work was recommended by the archaeologists.

3.7.3.3 Balance of perimeter (Archaeological Study Areas 4, 5, 6)

For the remainder of the plant, referred to as the balance of the perimeter, archaeological investigations were initiated in early 2012 to locate, document, and evaluate prehistoric archaeological sites in all areas outside of the OSDC Study Areas. The approximate acreage for these three areas is as follows: Archaeological Study Area 4 (381 acres), Archaeological Study Area 5 (690 acres), and Archaeological Study Area 6 (338 acres) for a total of 1,409 acres.

The results of the individual archaeological surveys have been submitted to the OHPO and consulting parties for information. A summary report that will document the findings of the surveys is in development. This summary report will be submitted to the OHPO and consulting parties for information as well.

3.7.4 Transportation

Activities at PORTS are supported by a system of transportation infrastructure that consists of roads, railroads, barges, and airports.

3.7.4.1 Roads

Two of southern Ohio’s major highway systems, U.S. Route 23 and State Route 32/124, provide access to PORTS (Figure 3.11). Both routes are four lanes with U.S. Route 23 traversing north-south and State Route 32 traversing east-west. The plant is 3.5 miles from the U.S. Route 23 and State Route 32/124 interchange. State Route 32/124/50 runs 185 miles east-west from Cincinnati through Piketon to Parkersburg, West Virginia. To the west, State Route 32 provides access to Cincinnati's three interstate highways, I-71, I-74, and I-75. To the east, State Route 32/50 is linked with I-77. Approximately 70 miles north of the plant, U.S. Route 23 intersects I-70, I-71, and I-270. Vehicles also may access I-64 approximately 35 miles southeast of Portsmouth.

The main access road for PORTS has a four-lane interchange with U.S. Route 23. The main access road is closed to general public access and connects to Perimeter Road, which encircles the fenced portion of the plant. Smaller roads that intersect with Perimeter Road from four directions provide access to inner portions of the plant. The buildings and facilities are serviced with a system of roads and streets, which generally follow a north-south grid. This system is in generally good condition because of road repaving projects (NRC 2006b).

As discussed above, there are two access roads to PORTS, U.S. Route 23 and State Route 32. Table 3.4 provides the annual average daily traffic for these roads. Load limits on these routes (85,000 lb) are controlled by the ORC gross vehicle weight. Special overload permitting is available (NRC 2006b).

Table 3.4. Traffic Conditions on Access Roads to PORTS

Access Road	Annual Average Daily Traffic
U.S. Route 23, entrance to PORTS	14,490
State Route 32 and U.S. Route 23	7,700

Source: Ohio Department of Transportation 2011.

PORTS = Portsmouth Gaseous Diffusion Plant

Except during plant shift changes, traffic levels on the plant access roads and Perimeter Road are low. Peak traffic flows occur at shift changes, and the principal traffic problem areas during peak morning/afternoon traffic are locations where parking lot access roads meet Perimeter Road (NRC 2006b).

3.7.4.2 Railroads

Two railroad carriers, CSX and Norfolk Southern, serve Pike County. The CSX system provides access to other rail carriers. Railroad track in the vicinity of Piketon allows a maximum train speed of 60 miles/hour (DOE 2004).

A railroad system is located at PORTS. The Norfolk Southern railroad connects to the CSX main rail system via a main rail spur entering the northwest portion of PORTS. Approximately 17 miles of track lie within the boundaries of PORTS. However, only approximately one-third of the tracks are currently in service. Several track configurations (switching capabilities) are possible within the plant. The on-PORTS railroad system is used infrequently, approximately one train per week (DOE 2004).

3.7.4.3 Barges

PORTS can be served indirectly by barge transportation on the Ohio River. However, use of the Ohio River barge terminals would require initial transportation of loads over public roads leading from PORTS to the barge terminal in the city of Portsmouth. The bulk materials-handling facility at the Portsmouth Barge Terminal is available for transporting bulk materials and heavy-unit loads. All heavy-unit loading is done by mobile crane or barge-mounted crane at the open-air terminal. The Ohio River provides barge access to the Gulf of Mexico via the Mississippi River or the Tennessee-Tombigbee Waterway. Travel time to New Orleans is 14 to 16 days. A barge trip to St. Louis takes 7 to 9 days, and a trip to Pittsburgh takes 3 to 4 days. The USACE maintains the Ohio River at a minimum channel width of 800 ft and a depth of 9 ft (NRC 2006a).

3.7.4.4 Airports

Because of the relatively isolated location of PORTS, commercial air service is limited. The nearest airport is the Greater Portsmouth Regional Airport, located approximately 15 miles south of the plant. This airport has dual runways and T-hangers and is operated by Chasteen Aviation, Inc. The airport mostly serves private aircraft owners and business travelers. There are no regularly scheduled commercial flights; however, charter service is available. Another nearby airport, the Pike County

Airport, is located just north of Waverly. This facility is similar in size and makeup to the Greater Portsmouth Regional Airport. Three international airports are located within a 2-hour drive of the plant: Cincinnati/Northern Kentucky International Airport, Dayton International Airport, and Port Columbus International Airport.

3.8 ECOLOGY

This section describes the existing ecological environment at PORTS and in its vicinity. It includes descriptions of terrestrial resources (flora and fauna); aquatic resources; rare, threatened, and endangered species; wetlands; and environmentally sensitive areas. This section describes the ecological resources present at PORTS.

3.8.1 Terrestrial Resources

Terrestrial habitat types and the flora and fauna that depend upon them are described in this section of the report.

3.8.1.1 Flora

PORTS and the surrounding area contain diverse terrestrial habitat types representing many successional stages in ecosystem development. A terrestrial community is described by the dominant vegetation species that characterize the community. The following 10 terrestrial habitat types (DOE 2001b, NRC 2006a) have been identified at PORTS:

- Old field areas – Early successional stage of disturbed areas dominated by tall weeds, shade-intolerant trees, and shrubs

- Scrub thicket – Later successional stage covering old field areas dominated by dense thickets of small trees

- Managed grassland – Open areas actively maintained and dominated by grasses

- Upland mixed hardwood forest – Mesic to dry upland areas dominated by black walnut (*Juglans nigra*), black locust (*Robinia pseudoacacia*), honey locust (*Gleditsia triacanthos*), black cherry (*Prunus serotina*), and persimmon (*Diospyros virginiana*)

- Pine forest – Advanced successional stage following scrub thicket; the overstory dominated by Virginia pine (*Pinus virginiana*)

- Pine plantation – Nearly pure stands of Virginia pines

- Oak-hickory forest – Well-drained upland soils; white oak (*Quercus alba*) and shagbark hickory (*Carya ovata*) are the most dominant of the oaks and hickories

- Riparian forest – Periodically flooded, low areas associated with streams, dominated by cottonwood (*Populus deltoides*), sycamore (*Platanus occidentalis*), willows (*Salix sp.*), silver maple (*Acer saccharinum),* and black walnut

- Beech-maple forest – Undisturbed areas dominated by American beech (*Fagus grandifolia*) and sugar maple (*Acer saccharum*)

- Maple forest – Dominated by sugar maple and other shade-tolerant species.

The most common type of vegetation on PORTS is managed grassland, which makes up approximately 30 percent of the total area of the plant. Oak-hickory forest covers approximately 17 percent, and upland mixed hardwood forest covers approximately 11 percent (NRC 2006a). The areas covered by each habitat type are presented in Table 3.5.

Table 3.5. Terrestrial Habitat Types at PORTS

Habitat Type	**Approximate Total Area (Acres)**	**Approximate Number of Communities**	**Percent of Total Area**[a]
Managed grassland	1,102	Numerous[b]	30
Oak-hickory forest	632	14	17.2
Old field	420	10	11.4
Upland mixed hardwood forest	400	20	10.9
Riparian forest	153	10	4.2
Maple forest	128	7	3.5
Scrub thicket	79	10	2.2
Pine forest	69	10	1.9
Beech-maple forest	5	1	0.1
Old white pine plantation with mixed hardwoods	5	1	0.1

Source: NRC 2006a

[a] Total plant area is approximately 3,777 acres. Approximately 629 acres (16.9 percent) of the total area is covered by buildings, parking lots, and roads. The remainder of the total plant area contains aquatic habitat.
[b] This habitat is interspersed between buildings and paved areas across the plant.

NRC = U.S. Nuclear Regulatory Commission

Within the central area surrounded by Perimeter Road, PORTS consists primarily of open grassland (including maintained grassy areas) and developed areas consisting of buildings, paved areas, and storage yards. The vegetative cover in the area surrounding the PORTS Facility consists mostly of hardwood forests and field crops (NRC 2006a).

In 2011, Ohio University initiated a plant-wide habitat mapping project that was completed in late 2012. This project used LiDAR data along with extensive field surveys to provide more detailed habitat delineation than previously available at PORTS. The final report quantifies the overall ecological quality of the mapped habitat. An interim report provided habitat mapping information related to the study areas under consideration in this RI/FS report (Ohio University 2012).

3.8.1.2 Fauna

Several species of wildlife have been observed within the PORTS property boundary. Forty-nine mammals have ranges that include PORTS, but only 27 of those have been observed on the reservation. The most abundant mammals at PORTS include the white-footed mouse (*Peromyscus leucopus*) and the short-tailed shrew (*Blarina brevicauda*). An area of deciduous sugar maple forest along the Northwest

Tributary stream corridor is the only identified area at PORTS that may be suitable habitat (summer months) for the Indiana bat (*Myotis sodalis*), a federal-listed endangered species. Larger mammals present include the white-tailed deer (*Odocoileus virginianus*), the eastern cottontail rabbit (*Sylvilagus floridanus*), and the opossum (*Didelphis virginiania*) (DOE 1996f).

One hundred and fourteen bird species, including year-round residents, winter residents, and migratory species, have been observed at PORTS. These species include raptors (red-tailed hawk [*Buteo jamaicensis*]), aquatic foul (mallard [*Anas platyrynchos*] and wood duck [*Aix sponsa*]), game birds (wild turkey [*Meleagris gallopavo*]), and nongame bird species (nuthatches [*Sitta sp*.] and wrens [*Troglodytes sp*.]). Eleven species of reptiles and six species of amphibians have been observed at PORTS. The most common of these include the eastern box turtle (*Terrapene carolina*), black rat snake (*Elaphe obsolete*), northern black racer (*Coluber constrictor constrictor*), American toad (*Bufo americanus*), and northern dusky salamander *(Desmognathus fuscus*) (NRC 2006a). Common orders of insects found at PORTS include Homoptera (cicadas and aphids), Hymenoptera (bees, wasps, and ants), Diptera (flies), Coleoptera (beetles), and Orthoptera (grasshoppers) (Battelle Memorial Institute 1976).

Common species occurring in open grassland areas include the eastern cottontail rabbit (*Sylvilagus floridanus*), meadow vole (*Rodentia muridae*), and eastern meadowlark (*Sturnella magna*). Small wooded areas support numerous woodland and forest edge species such as raccoon (*Procyon lotor*), gray squirrel (*Sciurus carolinensis*), red-headed woodpecker (*Melanerpes erythrocephalus*), cardinal (*Cardinalis cardinalis*), white-breasted nuthatch (*Sitta carolinensis*), and yellow-rumped warbler (*Dendroica coronata*). Species that occur in the open grasslands and forest edges that are either actively managed (mowed) or adjacent to developed areas are tolerant of human activities and disturbances (NRC 2006a).

3.8.2 Aquatic Resources

The aquatic habitats on PORTS include the various man-made holding ponds, ephemeral ponds, streams, and intermittent streams that flow from or through PORTS. The three major aquatic habitats include Little Beaver Creek, the West Drainage Ditch, and the Southwest Drainage Ditch, which flows out of the Southwest Holding Pond. All three of these surface water bodies discharge into the Scioto River. Little Beaver Creek and the West Drainage Ditch are designated as warm water habitats. Warm water habitats are capable of supporting and maintaining a balanced, integrated, adaptive community of warm water aquatic organisms having a diverse species composition and functional organization. The aquatic habitat associated with Little Beaver Creek supports good to exceptional fish communities downstream of the X-230-J7 discharge from PORTS, and fair fish communities upstream because of the intermittent stream flow (NRC 2006a).

Most of the aquatic resources at PORTS include populations of fish, amphibians, reptiles, invertebrates, and periphyton, all associated with streams and other surface waters. The most common of the 34 total fish species and four hybrids found in Little Beaver Creek are the bluntnose minnow (*Pimephales notatus*), central stoneroller (*Campostoma anomalum*), creek chub (*Semotilus atromaculatus*), rainbow darter (*Etheostoma caeruleum*), spotfin shiner (*Cyprinella spiloptera*), and striped shiner (*Luxilus chrysocephalus*) (NRC 2006a, DOE 2007b).

A classification effort in Study Area D identified 38 streams in the area. Of the 38 streams identified in Study Area D, sections of only three were determined to be Class IIIA PHWH; there were no Class IIIB streams. All streams within an area for permanent waste disposal were identified as lower quality classes, Class I and II. Table 3.6 presents a summary of the result of the classification study.

Table 3.6. Summary of PHWH Stream Classification

Provisional Aquatic Life Use Designation	Total Length (ft)
Modified Class I PHWH	2,725
Class I PHWH	6,357
Modified Class II PHWH	2,842
Class II PHWH	19,236
Class IIIA PHWH	5,103
WWH	678
Total	**36,941**

PHWH = Primary Headwater Habitat
WWH = Warmwater Habitat

3.8.3 Wetlands

The USACE defines wetlands as “those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.” Wetlands usually include swamps, marshes, bogs, and similar areas. In identifying a wetland, three characteristics should be met. The first is the presence of hydrophytic vegetation that has morphological or physiological adaptations to grow, compete, or persist in anaerobic soil conditions. Second, hydric soils are present and possess characteristics that are associated with reducing soil conditions. Third, the area must be inundated or saturated to the surface at sometime during the growing season of the prevalent vegetation (DOE 2004).

A wetlands survey of PORTS was conducted in 1995 (Lockheed Martin Energy Systems, Inc. [LMES] 1996). The results of that survey found that PORTS contains 45 wetlands (41 jurisdictional and four nonjurisdictional) totaling about 34 acres, excluding retention ponds and streams (Table 3.7). Jurisdictional wetlands fall under the protection of Section 404 of the *Clean Water Act*; DOE and State of Ohio regulations, as well as EO 11990, protect both jurisdictional and nonjurisdictional wetlands. Most of the wetlands are associated with wet fields, areas of previous disturbance, drainage ditches, or wet areas along roads and railroad tracks. Palustrine forested wetlands occur along Little Beaver Creek (DOE 2004). An updated evaluation of Study Area D was conducted in 2013 (DOE 2013b). Table 3.8 presents a summary of the Ohio EPA Anti-Degradation Designation (category) of the 24 wetlands identified during this study. No high-quality Category 3 wetlands were identified in Study Area D. There is good correlation to the jurisdictional wetlands found in the area in a 1996 study, but generally, the wetlands are now smaller. The details of the wetlands can be found in Section 2.2.2.3.

2	8	W08, W10, W12, W15, W17, W18, W21, W22	3.369

Ohio EPA = Ohio Environmental Protection Agency

3.8.4 Rare, Threatened, and Endangered Species

The Endangered Species Act of 1973 provides federal protection to species, and their habitats, that are listed as federal threatened or endangered species. A federal threatened species is defined as any species likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range. A federal endangered species is defined as any species in danger of extinction throughout all or a significant portion of its range (50 *CFR* 17). Ohio Statutes 1518 and 1531 provide protection for state-listed threatened and endangered (T&E) species. The ODNR defines a state endangered species as “a native species or subspecies threatened with extirpation from the state.” A state threatened species is defined as “a species or subspecies whose survival in Ohio is not in immediate jeopardy, but to which a threat exists.” A species of concern is defined as “a species or subspecies which might become threatened in Ohio under continued or increased stress.” A special interest species is defined as “a species that occurs periodically and is capable of breeding in Ohio.”

The potential existence of federal and state endangered, threatened, and rare species, as well as candidate species, in the vicinity of PORTS was determined through a review of previously prepared NEPA documents, by reviewing the results of previous studies, and through prior consultation with the U.S. Fish and Wildlife Service (USFWS) and the ODNR, Division of Wildlife and Division of Natural Areas and Preserves. No occurrence of federal-listed plant or animal species has been documented at PORTS (DOE 2004, DOE 2007b).

Previous consultation with the USFWS has indicated that the Indiana bat (*Myotis sodalis*) is the only federal-listed endangered species whose home range includes PORTS. Information from the ODNR identified several state-listed endangered, threatened, and special interest species within 1 mile of PORTS; however, database searches did not identify either species within the PORTS boundary. Consultation was initiated again in 2012 with USFWS regarding the potential for the Indiana bat at PORTS. The USFWS indicated that they had no record of Indiana bats being sighted or caught in Pike County, Ohio, but they confirmed that the species is still federally listed and their home range does include PORTS.

An additional review of previously prepared NEPA documents and studies also indicated that the Indiana bat, sharp-shinned hawk (*Accipiter striatus*), Carolina yellow-eyed grass (*Xyris difformis*), Virginia meadow-beauty (*Rhexia virginica*), and rough green snake (*Opheodrys aestivus*) may occur at PORTS. Other species that have been identified in the region, but not observed on PORTS, include the timber rattlesnake and long-beaked arrowhead (*Sagittaria australis*) (NRC 2006a). Table 3.9 lists the federal- and state-listed endangered, threatened, potentially threatened, and special concern species in the vicinity of PORTS.

Table 3.9. Federal- and State-listed Endangered, Threatened, Potentially Threatened, and Special Concern Terrestrial Species near PORTS

Common Name	Scientific Name	Status[a] Federal	State
Indiana bat	*Myotis sodalis*	E	E
Sharp-shinned hawk	*Accipiter striatus*	NL	E
Timber rattlesnake	*Crotalus horridus*	NL	E
Rough green snake	*Opheodrys aestivus*	NL	S
Virginia meadow-beauty	*Rhexia virginica*	NL	P
Carolina yellow-eyed grass	*Xyris difformis*	NL	E
Long-beaked arrowhead	*Sagittaria australis*	NL	T

Source: NRC 2006a

Only the sharp-shinned hawk, rough green snake, Virginia meadow-beauty, and Carolina yellow-eyed grass have been observed at PORTS.

[a] E – endangered; P – potentially threatened; S – species of concern; T – threatened; NL – not listed.

NRC = U.S. Nuclear Regulatory Commission
PORTS = Portsmouth Gaseous Diffusion Plant

Past and recent consultations with the USFWS indicate that some of the riparian areas on PORTS may be suitable summer habitat for the Indiana bat. Roosting and nursery sites may include forested areas with loose barked trees and standing dead trees. Potential summer habitat for the Indiana bat has been identified within the corridors along Little Beaver Creek in the northern portion of the plant and along the Northwest Tributary stream. The Northwest Tributary begins just southwest of the Don Marquis substation and flows approximately 3,200 ft before leaving the PORTS property. It then proceeds on to its confluence with Little Beaver Creek. In 1994 and 1996, DOE conducted on-PORTS surveys to identify suitable bat habitat and then conducted mist netting in those areas to determine if Indiana bats were present. The surveys identified these two potential habitat areas for Indiana bats and the mist netting resulted in the documentation of four different species of bats in these two riparian areas, but no Indiana bats were found at PORTS (NRC 2006a, DOE 2007b). Another bat mist-net survey was conducted in May 2011. During this survey, four nights of sampling resulted in the capture of eight bats, but no Indiana bats were observed (EnviroScience 2011). Based on USFWS approval of a mist net plan, a second mist net survey was conducted in OSDC Study Area D in July and August 2013 over 10 nights. No Indiana bats were found, but nine northern long-eared bats were captured, inventoried, and released along with four other species. Ohio University conducted a detailed habitat mapping study in 2012. Findings from this study, using updated guidelines, are that Indiana bat habitat may be more extensive than indicated in prior studies. The primary trees that produce exfoliating bark and nesting cavities (e.g., sycamore and shagbark hickory) are abundant in the older forest habitats (Ohio University 2012). Discussion will continue with USFWS to ensure the latest species listings are understood and that USFWS has all data that is collected at PORTS concerning rare, threatened, or endangered species.

Past isolated sightings of state-listed species on PORTS include the sharp-shinned hawk and the rough green snake, but no recent sightings have been reported. The Virginia meadow-beauty has been found near the X-611A Old Lime Sludge Lagoons, and Carolina yellow-eyed grass has been tentatively identified at the X-611B Sludge Lagoon. The Virginia meadow beauty is associated with the wetlands of the former sludge lagoon, and its preferred habitat is on wet, sandy soils, particularly in sandy swamps. The Carolina yellow-eyed grass was observed in 1994; however, formal documentation of the species could not be performed because the grass was not in fruit or flower. Carolina yellow-eyed grass prefers wet peaty or sandy soils typically found in marshes or bogs (NRC 2006a). Several additional state-listed plant species have been preliminarily identified during the recent habitat mapping project by Ohio University.

The Ohio EPA previously determined that two state endangered fish species and four state threatened fish species exist near PORTS, but they are restricted to the Scioto River. Little Beaver Creek, the main body of water running through PORTS, does not provide sufficient habitat to support threatened or endangered species of fish (NRC 2006a).

3.8.5 Environmentally Sensitive Areas

In the immediate area surrounding PORTS (within 5 miles), no environmentally sensitive areas are present. This includes state and national parks, conservation areas, wild and scenic rivers, and other areas of recreational, ecological, scenic, or aesthetic importance (NRC 2006a).

Several potential environmentally sensitive areas are located within the PORTS boundary, including areas where Ohio endangered or threatened species have been observed, wetland areas, and the riparian areas along Little Beaver Creek and its Northwest Tributary. Additional studies being completed by Ohio University may provide locations that harbor listed, high-interest plant species. No federally-listed plant species have been observed during the current study but some state listed species were tentatively identified and were revisited during the 2012 field season (Ohio University 2012). The specific sensitive areas previously identified are as follows:

- The Northwest Tributary stream corridor is considered a sensitive area because it represents the best potential habitat for bats at PORTS, although recent studies indicate bat habitat may be more extensive than previously indicated.

- The area near the X-611B Sludge Lagoon should be considered a sensitive area because of the possible presence of Carolina yellow-eyed grass, which was observed at PORTS in 1994 (DOE 1996f).

- The area near the X-611A Old Lime Sludge Lagoons is a sensitive area because the Virginia meadow-beauty plant species was identified at the base of the dike. Wetlands also are present near this area.

HIGHLIGHTS OF SECTION 3

- Immediate plant area is located on a thick layer of clay and silt. Shallow bedrock is present outside the main plant area.

- Off-PORTS groundwater transport pathways exist to the south in Quadrant I. Groundwater over most of the PORTS discharges to surface water.

- Rural residents exist at the plant boundary.

- A number of sensitive resources (e.g., cultural, streams, and wetlands) are present at PORTS and specifically at Study Area D. There were no Class IIIB streams or Ohio Category 3 wetlands found in Study Area D.

NEXT STEP: SECTION 4 DEFINES THE SOURCE TERM (WASTE STREAMS)

4. BASIS FOR PROJECTED WASTE STREAMS AND VOLUMES AND POTENTIAL UNCERTAINTIES

Providing information to support development of a CSM continues in this section. Section 2 presented data that were obtained from investigations and used in defining elements of the CSM. Section 3 provided an understanding of the physical features of PORTS that will have a bearing on the fate of contaminants, along with their transport mechanisms and the location of potential current receptors and sensitive resources. The intent of Section 4 is to present the PORTS waste disposition volumes and characterization information to define the source term in the CSM. Section 4 supports the ability for this evaluation to examine and account for future wastes (either EC-1 or EC-2), including those that will be generated under other actions (RC-4) and the remaining RCRA corrective action program decisions (RC-2).

To provide source term information, Section 4 is divided into two sections. The first (Section 4.1) provides general and specific waste volume information by waste form (soil, concrete, asbestos, other building waste, etc.), waste type (low-level [radioactive] waste [LLW], hazardous waste, etc.), and location (or generator project). Section 4.1 also introduces the waste volumes that will be evaluated. Section 4.2 describes the waste characterization information known at this time. The uncertainties associated with the information in Sections 4.1 and 4.2 are then presented in Section 4.3.

This section discusses the D&D waste generated during DFF&O activities (RC-1, both EC-1 and EC-2), the majority of it from the three large process buildings. There are smaller volumes of D&D waste associated with support structures and buildings and with residual soil and soil which otherwise must be excavated as an integral part of D&D (see, DFF&O definition of D&D defined in paragraph 5e). The residual soil and soil which otherwise must be excavated as an integral part of D&D are hereinafter referred to in this document, for ease of reference, as “residual soil” and are limited by the definition of D&D in the DFF&O.

Undefined volumes of other waste (RC-4, either EC-1 or EC-2) may be generated. Additionally, there are other environmental media wastes that may be generated pursuant to the Ohio Consent Decree (RC-2, EC-1). The exact volume of soil assumed to be generated under the RCRA corrective action program that might potentially be placed in a potential OSDC after appropriate authorization is not defined because RAOs for future RCRA actions have not yet been established, and the soils beneath the process buildings and across much of PORTS have not been fully characterized and the need for excavation is not yet established. Nevertheless, in the interest of being comprehensive, an estimate is provided.

For all of these potential waste streams (RC-1, RC-2, RC-4), the primary contaminants at PORTS are radionuclides, but other contaminants such as metals and organics are present as well. In general, most of the waste streams generated under any of the regulatory programs would likely be classified as LLW. The information in this section is sufficient to define waste volumes and characteristics to support alternative development and evaluation, as well as to assess potential future threats if no action is taken.

Appendix E presents the waste volumes by buildings and provides details of the volume estimates for waste under the DFF&O and Ohio Consent Decree. It includes information that was in the Fluor-B&W Portsmouth LLC Mass Flow Database as of December 2011. This database is maintained under configuration control and is updated as additional information becomes available. No scope has been identified for other actions (RC-4), so there are no entries in Appendix E for these wastes.

4.1 FUTURE WASTE VOLUME PROJECTIONS

The specific volumes and composition of waste that would be generated from the implementation of PORTS D&D actions (RC-1), as well as from other non-D&D PORTS clean-up activities (RC-2, RC-4), are being developed under project-specific documents in parallel with this RI/FS. The volumes and composition of the waste evaluated in this RI/FS (RC-1, RC-2) are presented in Table 4.1. Because there is no scope yet assigned to the regulatory category RC-4, no volumes for this waste are presented in Table 4.1. The waste volume information used in this RI/FS analysis is based on what is known at this time from PORTS information and lessons learned from similar DOE projects. The information in this section is consistent with planning assumptions established in the waste disposition RI/FS Work Plan (DOE 2012a). The waste forecast for PORTS has been developed and examined over many years and was formalized in the DOE-approved Critical Decision-1 baseline document. Since that time, the waste generation forecast has been reviewed and revised as preparations and plans for PORTS D&D have matured.

Table 4.1. Waste Volumes (RC-1, RC-2) by Form

Waste Form	Volume (cy)
D&D waste (RC-1)	
Asbestos (EC-2)	3,000
Concrete (EC-2)	400,000
Other building waste (EC-2)	629,000
Process equipment (EC-2)	272,000
Residual Soil (EC-1)	53,000
Materials with high recycle potential	110,000
Total D&D waste (RC-1)	**1,467,000**
Ohio Consent Decree/Three Party Order waste (may be generated pursuant to corrective action activities-RC-2)	
Contaminated soil (RC-2, EC-1)	710,000
Total D&D and Ohio Consent Decree/Three Party Order waste (RC-1, RC-2 both EC-1, EC-2)	**2,177,000**

General Notes:
1. Volume estimates represent uncontainerized waste with no adjustments for expansion or compaction.
2. Numbers have been rounded.
3. Waste from D&D of utilities and infrastructure are included as other building waste.
4. Asbestos waste consists of any material, such as insulation, that contains asbestos fibers, including transite siding, building pipe, floor tile, and cable insulation. It is likely that asbestos-containing material will be prevalent in most buildings.
5. Concrete waste consists of demolition and building materials, including concrete pads, floors, pillars, basements, and concrete building construction materials.
6. Other building waste is waste demolition material from razing buildings, including wood, rubber, concrete that could not be separated from the rubble, metallic items other than process equipment, siding, gypsum, roofing material, flooring, and brick.
7. Process equipment waste consists of equipment and associated appurtenances directly used for uranium enrichment, including compressors, converters, motors, process piping, and valves.
8. D&D residual soil (RC-1, EC-1) volume refers to residual soil that adheres to the concrete foundations or otherwise must be excavated as part of D&D activities.
9. Ohio Consent Decree/Three Party Order waste (RC-2) cannot be disposed of in an OSDC without DOE obtaining the appropriate authorization and/or exemptions from Ohio EPA, and such waste would have to meet the Ohio EPA approved WAC.

D&D = decontamination and decommissioning
DOE = U.S. Department of Energy
EC = engineering category
Ohio EPA = Ohio Environmental Protection Agency
OSDC = on-Site disposal cell
RC = regulatory category
WAC = waste acceptance criteria

4.1.1 D&D Waste Volume (RC-1) Description

The Site-wide Waste Disposition Evaluation Project under the DFF&O is limited in scope to determining the most appropriate waste disposition outlet for potential future D&D waste that may be generated at PORTS. This section focuses on the waste volumes anticipated by D&D of the Portsmouth GDP under the DFF&O (RC-1, both EC-1 and EC-2). Currently, the total waste volume (RC-1, EC-1 and EC-2) estimated to be generated from D&D of the three large gaseous diffusion process buildings, numerous smaller buildings and/or facilities, and man-made structures on PORTS is 1.47 million cy, including 53,000 cy of residual soil (RC-1, EC-1). The distribution of the volume expected to be generated from implementing decisions made under the DFF&O is shown in Table 4.1 and Figure 4.1 by waste form.

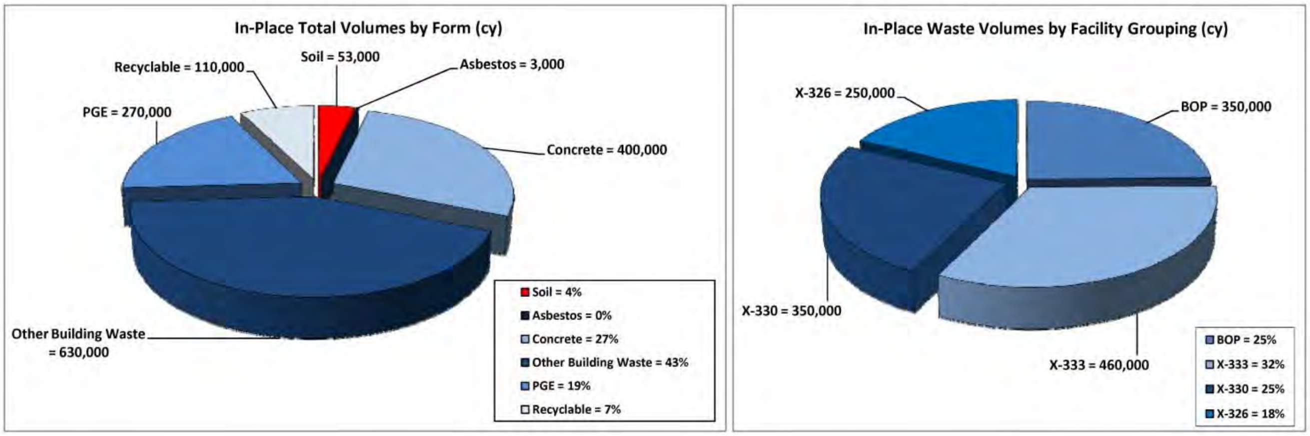

Figure 4.1. PORTS D&D Volumes (RC-1) by Facility Grouping and Form

The vast majority of waste (approximately 75 percent or 1.1 million cy) that would be generated during D&D of PORTS would originate from the three large gaseous diffusion process buildings, X-326, X-330, and X-333. The waste volumes include the structure of each facility, all process and industrial equipment within each facility, and facility slabs. The balance of the expected waste volume would be from hundreds of smaller buildings and man-made structures and is estimated at 0.35 million cy of waste or approximately 25 percent of the total PORTS D&D waste forecast.

To determine potential disposal options for the D&D waste, candidate waste streams are further delineated by regulatory classification, in addition to the waste forms and associated volumes already provided. Expected regulatory waste types include the following:

- Hazardous waste defined by RCRA and State of Ohio *OAC* 3745-52-11
- Waste defined under the Toxic Substances Control Act of 1976 (TSCA)
- Solid waste defined by the State of Ohio *OAC* 3745-27-01
- Construction and demolition debris as defined by *OAC* 3745-400
- LLW as defined by DOE Order 435.1.

In addition, any of the waste types could be radiologically contaminated, rendering them LLW as defined in DOE Manual 435.1-1, *Radioactive Waste Management.* Table 4.2 presents a breakdown of the varying regulatory types of waste that are anticipated to be generated under D&D of PORTS not including 110,000 cy of material that may be recycleable.

Table 4.2. Details of D&D Waste Volumes (RC-1) by Regulatory Waste Type

Type of D&D Waste (RC-1)	Estimated Volume[a] (cy)
RCRA Hazardous-CAMU ineligible	400
RCRA Hazardous-CAMU eligible	53,000
TSCA	0
C&DD	32,000
Solid	10,200
LLW/RCRA Hazardous-CAMU ineligible	100
LLW/RCRA Hazardous-CAMU eligible	0
LLW/TSCA	37,000
LLW/C&DD	786,800
LLW/Solid	437,500
Infectious waste	0

[a] Volume assumptions regarding CAMU-eligible and CAMU-ineligible wastes were made for the purpose of evaluating alternatives. DOE has not proposed a CAMU yet and, therefore, no determinations have been made regarding what waste is or is not CAMU eligible. DOE may need to revise these estimates in the future.

C&DD = construction and demolition debris
CAMU = Corrective Action Management Unit
D&D = decontamination and decommissioning
DOE = U.S. Department of Energy
LLW = low-level (radioactive) waste
RC = regulatory category
RCRA = Resource Conservation and Recovery Act of 1976, as amended
TSCA = Toxic Substances Control Act of 1976

This waste forecast estimate has appropriate accuracy and precision for assessing and estimating remedial alternatives developed in this RI/FS. The volume estimate evolves from field studies; process knowledge; facility walkdowns, including measurements of building structures and components; and engineering studies, including review of as-built drawings.

DOE is committed to recycling and/or reuse of materials from the PORTS D&D Project, regardless of the selected remedy. Recycling and/or reuse decisions will be made for discrete materials and waste streams across all phases of the D&D project, including the RI/FS, remedial design, and remedial actions. Decisions to recycle and/or reuse materials will be made following an evaluation of relevant factors and considerations. A few of the primary benefits of material recycling and/or reuse in the context of this RI/FS include conserving disposal capacity, regardless of disposal location, and meeting EO requirements (EO 13514) and DOE Order requirements (DOE Order 436.1) on pollution prevention and waste minimization. For the purposes of developing and evaluating remedial action alternatives in this FS, an estimate of 110,000 cy of recyclable material has been included in each of the action-based remedial alternatives, based on an initial evaluation of the scope of anticipated waste streams included in the D&D project. The actual volume to be recycled and/or reused may change as the recycling plans are developed and specific recycling opportunities are identified.

4.1.2 Waste Associated with Fill

One of the alternatives that will be considered later in this document includes operation of a potential OSDC. When considering cell operations, all waste material that is not soil is considered as one waste form (EC-2) and includes asbestos, concrete, PGE, and other building waste as defined in Table 4.1. Operation of a disposal facility requires a ratio of fill to waste requiring soil (EC-2) (referred to as EC-1/EC-2 ratio) that would control the potential for future waste subsidence, thereby protecting the final cap. Excessive void spaces created by the disposal of waste with void spaces (EC-2) alone can jeopardize the cap. Based on historical operations at other DOE landfills, the 2 to 1 EC-1/EC-2 ratio was selected as an average basis for volume and capacity calculations after size reduction, interior spaces are filled, and compaction at the disposal face occurs. The fill is used to prevent future settling of the waste and eventual failure of a final cover. Fill is always designated as having soil-like properties and therefore is categorized as EC-1. The actual fill needed for some of the waste will be notably less as boxes of containerized waste may have very little void space between the boxes. But, more fill may be needed for larger pieces of equipment to fill around the exterior of the shell. Fill is also used as daily cover and for internal berm construction. This fill does not include estimates needed to fill interior spaces. The EC-1/EC-2 ratio may be smaller or greater, depending on final design and operational requirements.

An evaluation of potential fill options is conducted in the FS portion of this document. Fill can be from off-PORTS or on-PORTS locations. On-PORTS fill could be generated from contaminated or clean areas. To obtain sufficient fill material to provide the appropriate EC-1/EC-2 ratio at a potential OSDC, there is the potential that some waste with void spaces (EC-2) might be excavated along with the fill that may require disposal. In this case, consideration must be given that there would be sufficient fill available to account for the additional excavated waste with void spaces (EC-2).

4.1.3 Non-D&D Waste (RC-2)

As described in the DFF&O SOW for RIs, information about anticipated waste streams is to be collected and presented. Section 4.1.1 presented the information about waste streams anticipated to be generated under the DFF&O. The DFF&O RI/FS SOW allows consideration of “Potential waste streams associated with environmental media cleanup activities to be conducted under the Ohio Consent Decree and for which DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste streams in any potential OSDC that might be constructed as a result of the Site-Wide Waste Disposition Evaluation Project.” Under the Ohio Consent Decree, significant volumes of contaminated soil and associated groundwater still require a remediation decision. Excavation may be a major component of the remediation decision. The impacts and implications of up to an estimated 710,000 cy of non-D&D contaminated soil (RC-2, EC-1) from the remaining environmental media cleanup activities under the Ohio Consent Decree are considered. The 710,000 cy is an estimate established for the purposes of conducting a complete and thorough evaluation of the alternatives. The actual volume of any non-D&D waste (RC-2) will be determined based on several factors, including the final Ohio Consent Decree remediation decision associated with such media. The decision to excavate or dispose of non-D&D waste (RC-2) is not being made under this project.

4.2 WASTE CHARACTERIZATION SUMMARY

This section discusses what is known about potential future generated waste volumes defined in Section 4.1 and presents the types of contamination that may be found. Identifying the types of contamination assures that any WAC that are developed or any identified disposal locations address the types of waste anticipated to be generated. Information from the almost 20-year-long cleanup of the facilities within the East Tennessee Technology Park (ETTP) in Oak Ridge, Tennessee, has been included in this section to provide additional information of the potential contamination levels that may be found.

Section 4.2.1 discusses information used to determine volumes of waste form and types for the process buildings (RC-1). Available quantitative PORTS sample results were provided in Section 2.2 (Tables 2.2 and 2.3). Section 4.2.2 discusses information that is available from ETTP to further understand some of the waste that may be generated from the PORTS facilities. Section 4.2.3 presents the PORTS-related contaminants that have been identified in environmental cleanup documents. They represent the types of contaminants that could be found in soil generated under the Ohio Consent Decree (RC-2), as well as contamination that may still be present in the buildings. Section 4.2.4 then summarizes Section 4.2 and what is known about the characteristics of the waste that is being considered for disposal under this decision.

4.2.1 PORTS Process Knowledge Summary for Process Buildings

A starting point for characterization of the D&D waste (RC-1) expected to be generated is identifying and understanding the processes that created radiological and/or hazardous waste. This leads to a better understanding of the potential contaminants in the waste. Evaluation of process knowledge is vital to defining the universe of potential contaminants, as well as the expected waste forms, waste types, and hazards associated with the waste. Most of the effort in developing waste types has focused on the three process buildings because D&D at these facilities would generate a majority of the waste volume. Constituents that were present in the buildings (or are still present) are likely present in residual soil (RC-1, EC-1) that would be removed during D&D activities.

4.2.1.1 Radiological constituents

The primary radiological contaminants of concern (COCs) within the process buildings are uranium (uranium-234, uranium-235, and uranium-238) and technetium-99. Most of the technetium-99 was introduced into the cascade system either as direct feed of reactor returns or through feeding of Paducah product (UF_6) material. Radionuclides introduced into the gaseous diffusion system from the processing of reactor returns were typically generated through the plutonium uranium extraction (PUREX) process. The byproduct of this process was uranium trioxide (UO_3), which was returned to the uranium feed cycle for the production of UF_6 feed materials. The PUREX process was highly efficient at separating out fission products and transuranic elements from its product streams; however, for some radionuclides (primarily technetium-99), the PUREX separation process was not fully effective. These reactor returns were introduced into the gaseous diffusion process to facilitate increased production and reduced reliance on commercial uranium ore mining and milling. As a result, the contaminants present in the feed materials generated from reactor returns are known to have contained measurable concentrations of fission products and transuranic elements, including most notably technetium-99, neptunium-237, and plutonium-239.

Reactor-return-generated feed materials were introduced into the cascades at PORTS in one of two manners, either through the feeding of an intermediate UF_6 product from Paducah or through the direct feed of UF_6. Based on processing records, the majority of the uranium feed generated from reactor returns was introduced into the PORTS cascades after these materials were subjected to initial enrichment operations in Paducah. A much smaller fraction was introduced into the PORTS cascades as direct feeds (without any initial enrichment at an alternate facility). It might also be noted that after the late 1970s or early 1980s, direct feeding of uranium feed produced from reactor returns ceased. PORTS continued to receive a quantity of reactor returns feed materials from Paducah up to the shutdown of the PORTS process (TPMC 2006b).

Process equipment in the PORTS process buildings contained solid deposits of uranium compounds at the time of plant shutdown in 2001. These solid deposits formed during subatmospheric (low pressure) operations, primarily as a result of chemical reactions between UF_6 and moisture in ambient air that was introduced into the system during failure of equipment welds or tubing, or operational errors during equipment change-outs.

The solid deposits of uranium can be further defined as uranium holdup deposits or a uranium/fluoride passivation layer or deposition layer. The uranium holdup deposit is described as concentrations of uranium-bearing materials (requiring nuclear criticality safety controls) that have inadvertently accumulated in the systems and components. This uranium-bearing material is typically in the form of an encrustation formed as a result of the process gas in the system reacting with the moisture in the ambient air. Some uranium holdup deposits can exceed the nuclear criticality safety limits or levels determined for the WAC of the receiving facility. Deposits that do not meet the WAC of the receiving facility would need to be removed by segregation or treatment, or decontaminated for on-Site or off-Site disposal.

Another typical form of deposit within the cascade system is in the form of a uranium/fluoride passivation layer or deposition layer that is also defined as uranium-bearing material. This layer is described as a fine film deposited throughout the interior surfaces of the process gas systems and components. The deposition of the uranium/fluoride passivation layer may be characterized along with the waste of the process gas system and components. The D&D project will use screening techniques (NDA) to discern uranium holdup deposits from the uranium/fluoride passivation layer.

At shutdown, there was concern from a nuclear criticality safety standpoint that some of these deposits could have been above the always-safe mass (ASM) limit for enriched uranium. While shutdown of the PORTS gaseous diffusion process used lessons learned from Oak Ridge and followed rigid procedures to reduce risks, the chances of excessive hold-up material (or deposits) nevertheless exists. Field activities since shutdown included extensive NDA measurements to identify the potential presence of deposits above the ASM limits and to mitigate the risks. The nuclear criticality safety program requires that deposits exceeding the ASM limit must have additional controls to ensure safe operations. The ASM of enriched uranium is an amount slightly less than one-half of a minimum critical mass, which is the minimum amount of enriched uranium that can achieve criticality under optimum conditions of shape, moderation, and reflection. Depending on the uranium-235 enrichment of the material, ASM can range from a few hundred grams of uranium for HEU to several hundred pounds of uranium for LEU.

A project at PORTS was completed to reduce the size of the uranium holdup deposits to below ASM values. Extensive NDA measurements have been taken to determine the locations and sizes of uranium deposits; this program began at shutdown and continues. The NDA measurements consist of initial scans of process equipment to determine if deposits exist. The scans are then followed by more detailed measurements and analyses to determine the size and uranium-235 enrichment of the deposits. In addition to scans, Portsmouth GDP operations data and other process knowledge sources are essential for understanding enrichment levels and general waste characterization throughout the GDP process buildings. NDA and other measurement and sampling techniques are used to verify process knowledge assumptions. Improvements in NDA techniques and measurements have been made since 2001, and further measurements have been conducted using the improved NDA techniques. Deposits found to be in excess of ASM were chemically treated until subsequent NDA measurements confirmed the deposits had been reduced to below ASM, taking into account NDA uncertainty. One ASM deposit in the X-330 Building was the result of an equipment fire, and the resultant deposits are of different chemical forms and are expected to require physical removal.

As previously stated, uranium in the form of UF_6 traveled uniformly throughout the cascade and segregated according to its isotopic composition. Uranium-235 concentrated at the upper end of the cascade within the X-326 Building, while uranium-238 moved to the bottom-of-tails section of the cascade within the X-333 and X-330 Buildings. In the absence of wet air, uranium deposited in a fairly uniform thickness in the process equipment would be expected to be reflective of the enrichment values handled at that stage of the cascade. Where wet air leaked into the system, uranium deposits would form separately with an enrichment value reflective of the location within the cascade at that particular time.

Based on the NDA data available to date, the total uranium inventory in the process equipment is estimated to be 151,000 kg, of which 2,030 kg are uranium-235. This value is highly uncertain and Section 5.1.3 provides discussion on this uncertainty.

During gaseous diffusion operations, most of the technetium-99 was introduced to the PORTS cascade either as direct feed of reactor returns or through feeding of Paducah UF_6 product. Based on process records, a total of 64 kg of technetium-99 was fed to the PORTS cascade (BJC 2000). Previous estimates had estimated the total receipt of technetium-99 at PORTS to be as high as 85 kg compared to 207 kg and 692 kg introduced to Oak Ridge and Paducah, respectively (Bostick 2010). Technetium-99 is a fission product produced in nuclear reactors, and it tends to follow uranium through the reprocessing steps. The technetium-99 compounds were lighter than UF_6 and tended to adsorb onto interior surfaces of the process equipment and slowly move up through the enrichment process until withdrawn along with the uranium-235 product or discharged through chemical traps to the atmosphere. Much of this technetium-99, approximately 50 percent (TPMC 2006b), exited the process with the primary or secondary product streams. In addition, much of the technetium-99 introduced into PORTS was removed from the process equipment during plant upgrades in the late 1970s and early 1980s. The Cascade Improvement Program (CIP)/Cascade Uprating Program (CUP) included the removal and replacement of barrier materials in the X-333 Building and portions of the X-330 Building. The replacement of this barrier material may have further contributed to the reduction of technetium-99 values within the cascades. During the CIP/CUP Project, existing converters, compressors, and other process equipment were replaced with reworked process equipment that had been fully decontaminated prior to reworking.

In 1999, an estimate of technetium-99 remaining in the process buildings was compiled by DOE. At that time, approximately 35 kg of residual technetium-99 were estimated to be distributed within the cascades; however, the effect of the CIP/CUP Project having removed much of the remaining 35 kg was not considered (BJC 2000). Recent data from converters in X-326 and X-330 suggest that residual technetium-99 quantities are probably closer to 5.5 kg throughout all three buildings, with the mass of technetium-99 anticipated to be more heavily concentrated within the purge equipment of the X-326 Building (TPMC 2006b) and in the upper unit of the X-330 Building. This estimate of mass is highly uncertain. The uncertainties discussion in Section 5.1.3 provides more discussion on the uncertainties. USEC began biased process equipment sampling for technetium-99 and other constituents in February 2011, which is continuing to date (see Section 2). Overall, the sample results are comparable to similar converter samples taken in Oak Ridge, suggesting that technetium-99 bonded to the barrier material until saturated, then moved upward through the diffusion process.

Small quantities of transuranic isotopes, neptunium-237 and plutonium-239, are also suspected of being introduced into PORTS during the feeding of reprocessed uranium feed stock. These transuranic compounds were much less volatile than UF_6 and, therefore, would have been expected to primarily remain in the unfed heel within the UF_6 cylinders. A "smaller" portion of these transuranic isotopes is anticipated to have entered the process gas system. On the basis of their limited volatility, it is anticipated that once in the process gas system they would have tended to drop out and concentrate near the relevant cascade product feed points, which were primarily located in the X-330 Building. As with the technetium-99, equipment changes during CIP would have removed most transuranic isotopes that had entered the process equipment before that time. However, because most piping and some valving were not changed out, these transuranic isotopes are considered to be contaminants present in the process gas system. The feed piping between the X-342 Building/X-343 Building and various X-330 Building feed locations was not removed during the CIP. Therefore, residual concentrations of these contaminants may exist at these locations.

With the exception of routine maintenance of the top purge equipment, none of the process equipment in the X-326 Building was replaced during the CIP, nor were any of the units in the X-330 Building that are currently suspected of containing elevated technetium-99 levels. Because most piping and some valving were not changed out during CIP, any transuranic isotopes present in those process gas system elements would still be present.

Exterior surface uranium contamination exists in all three PORTS process buildings. Contamination resulted from maintenance activities and infrequent leaks of process gas during greater than atmospheric operations in the X-330 and X-333 Buildings. Both fixed and removable contamination can be found on the operating and cell floors. Contamination areas are posted as such, and exits are well-marked and supplied with exit monitoring equipment. Personal protective equipment (PPE) and contamination control procedures are used to reduce the risk of spreading contamination outside of marked and controlled areas.

Surface technetium-99 contamination can be found primarily in the southern portion of the upper floor of the X-326 Building in the vicinity of the purge cascades and, to a lesser extent, the southern portion of the X-330 Building upper floor. The PPE and contamination control procedures prevent the spread of technetium-99. Surface contamination resulting from processing reactor return material is below detection limits throughout the remainder of the process buildings.

Chemical trapping materials in the process buildings include alumina, such as aluminum oxide (Al_2O_3) and sodium fluoride (NaF). These trapping materials contain elevated concentrations of uranium, HF, technetium-99, and heavy metals. The alumina traps were used as final filtration before discharge of light gases to the atmosphere. Sodium fluoride was used to recover UF_6 from purge gas streams before return to the cascade and final purging. Magnesium fluoride (MgF_2) side-stream traps were installed in the X-326 Building (Cells 25-7-15, 17, and 19) to remove technetium-99 in the top of the cascade. This trapping system was successful in reducing the cascade technetium-99 inventory, but created a source of concentrated technetium-99 trap media. Also, there is an assumption that plutonium and neptunium may also be present on the magnesium fluoride trapping material (BJC 2000). The traps have been disconnected from the cascade and are currently compliantly stored in the X-326 Building (on the operating floor).

4.2.1.2 Hazardous contaminants

The primary hazardous COCs are PCBs, metals, asbestos, and strong oxidizing agents (DOE 2013a). PCBs from electrical capacitors, transformers, and impregnated ventilation gaskets; metals such as lead and silver solder from tube fittings and other applications; cadmium and other metals from alloys and trapping materials; strong oxidizing agents from the residual UF_6, fluorine; and HF are anticipated to be present.

Chemical hazards in the process buildings include coolant (R-114) that was used as the primary process coolant for the UF_6 gas. Residual amounts of the coolant may be present in coolant tanks or piping in the process buildings. A small amount of liquid coolant (fluorinated and/or chlorinated carbon compounds) may be found in the tails area of the X-330 Building. Miller’s Fluorinating Lubricant may be found in the cold recovery systems in X-330 and X-333. Miller’s Fluorinating Lubricant was used until the 1970s in the Beach Russ vacuum pumps and discontinued at that time, and Lapine Oil was used thereafter. Recirculating cooling water (RCW) was used as the secondary cooling medium for the R-114 coolant. Initially, the PORTS RCW treatment system contained hexavalent chromium to prevent corrosion. In the 1990s, treatment of the cooling water was changed to a more environmentally acceptable phosphate-based system. A recent demolition project of an RCW system (X-633 cooling towers) found detected levels of residual chromates. During demolition of the X-633 RCW Complex, metals and radiological constituents were detected above PORTS PRGs in the water in the pump house wet well, valve vaults, and the pump house floor drains (DOE 2009b). Therefore, residual chromate and phosphate compounds are anticipated in the RCW system within the three process buildings.

Residual amounts of hydrocarbon oils used to lubricate the process compressors and motors may be encountered in the lubricating oil headers, filters, tanks, and hydraulic lines, once drained from the system.

Asbestos-containing materials (ACMs) are present as building siding (transite), cell housings, insulation on steam lines, refrigeration systems, motor brakes, and process insulation. ACM may also be found in floor tile in various areas of the buildings. ACM is regulated by the NESHAP contained in 40 *CFR* 61, Subpart M. Friable ACM means any material containing more than 1 percent asbestos as determined using the method specified in 40 *CFR* 763, Subpart E, Appendix E, Section 1, Polarized Light Microscopy, that, when dry, can be crumbled, pulverized, or reduced to powder by hand pressure. If the asbestos content is less than 10 percent as determined by a method other than point counting by polarized light microscopy, the asbestos content must be verified by point counting.

NESHAP-Regulated ACM includes both friable ACM and nonfriable ACM that is or can/will become friable during the demolition activity. Friable asbestos and materials that can be made friable during demolition have to be removed prior to demolition and must be packaged appropriately. The asbestos NESHAP requires specific actions to control emissions and specifies “zero” visible emissions from activities relating to the transport and disposal of asbestos waste.

Category I material is defined as asbestos-containing resilient floor covering, asphalt roofing products, packings, and gaskets. Asbestos-containing mastic is also considered a Category I material (EPA 2011b). Category II material is defined as all remaining types of nonfriable ACM not included in Category I that, when dry, cannot be crumbled, pulverized, or reduced to powder by hand pressure.

The asbestos NESHAP specifies that Category I materials that are not in poor condition and not friable prior to demolition do not have to be removed, except where demolition will be by intentional burning. However, Regulated ACM and Category II materials (including transite) that have a high probability of being crumbled, pulverized, or reduced to powder as part of demolition must be removed before demolition begins unless properly contained.

Residual amounts of PCBs are anticipated in the X-330 and X-333 Building ventilation ducts, transformers, electrical switchgears, storage tanks, and capacitors, once oil is drained from the systems. The joints in the ventilation ducts were installed with PCB-impregnated gaskets as a fire retardant because these ducts were connected to the process motors and their shaft oil lubricating systems. During normal operations and failures, lube oil from the motors leaked into the ducts, soaked through the PCB-impregnated gaskets, and dripped onto the operating floors of the process buildings. Oil collection systems constructed of polyvinyl chloride piping were installed on the ventilation duct joints to collect the PCB-laden oils. In summary, the ventilation ducts and PCB oil-collection systems are known to contain regulated levels of PCBs, oils, and radionuclide contamination.

Residual amounts of strong oxidizing agents, such as elemental fluorine and chlorine trifluoride used in cell treatments for deposits, may be encountered in surge drums, process piping, or manifolds and piping where these agents were distributed to the process equipment.

Small amounts of mercury are contained in various specialized instruments essential to the proper functioning and operation of the process equipment. For example, mercury is commonly found in temperature/pressure contact switches, chemical traps, fire pull stations, and mercury vapor lamps used for high bay lighting (TPMC 2006b). The X-326 Building instrument and sampling lines contain small mercury traps that were used to remove corrosive gases within the line and prevent damage to the mass spectrometer line recorders.

Arsenic may be found primarily in the X-326 Building instrument lines and sampling lines as a result of treatment gases. Beryllium is present in aluminum compressor blades and compressor impellers in low parts per million quantities. Other metals such as arsenic, barium, cadmium, and lead may be found in association with the chemical trapping materials. For example, sources of lead contamination may include wall plugs, solder, electrical sheathing, and other common materials of construction. Standard waste characterization practices include careful examination of materials of construction to verify and quantify the presence of RCRA-regulated metals and other hazardous constituents.

In the auxiliary systems, the seal exhaust systems and process monitoring and control instrumentation were regularly exposed to process gas and are anticipated to be contaminated with uranium. Auxiliary systems that were not exposed to process gas and are not expected to be contaminated with uranium include the nitrogen distribution system, dry air distribution system, steam distribution system, coolant system, RCW system, lube oil system, and power systems.

The process buildings were constructed on concrete slabs ranging in thickness from 6 to 8 in. Neither chemical nor radionuclide contamination from the gaseous diffusion process is expected to have migrated into soils beneath the buildings. To date, soil samples have not been collected below the slab of the process buildings to verify this expectation.

Electrical and instrument tunnels run from beneath the process building control rooms to the X-300 Central Control Facility and the electrical switchyards. Instrument lines and electrical power cables are contained within these tunnels. Hazardous materials such as arsenic, silver and other solder agents, asbestos, and lead in the electrical cables and various electrical components may be encountered.

4.2.2 Data from the ETTP D&D Project for Key Buildings

PGE data from PORTS are the best data to represent the types and levels of contaminants that may be found in PORTS PGE waste streams. These data are presented in Section 2.2.1. The data recently collected at PORTS from the demolition of earlier buildings presented in Section 2.1.4 are the best representation of the type and levels of contaminants that may be found in future D&D waste streams (RC-1) from many of the PORTS support facilities. This information from PORTS can be supplemented with data from waste streams from the demolition of the structures of the process buildings or maintenance buildings at ETTP. Therefore, the data available from ETTP for similar buildings are also evaluated.

ETTP (formerly the K-25 GDP) had an identical mission to that of PORTS. The K-25 Building was the world’s first gaseous diffusion process building. After the process was demonstrated, the K-27, K-29, K-31, and K-33 gaseous diffusion process buildings were constructed on the current ETTP site. K-27 and most of the K-25 Building were shut down in the spring of 1964. The K-311-1/K-310-3 Top Purge Cascade was the only operating equipment in the K-25 Building after June 1964 (Shoemaker 2010). All remaining gaseous diffusion operations were ended in 1985. Since 1989, the ETTP mission has been environmental cleanup and reindustrialization. Both K-25 and PORTS enriched uranium for use as nuclear fuel in commercial and DOE nuclear power reactors, as well as for defense purposes (weapons).

For most of the operating life of ETTP and PORTS, both plants received slightly enriched uranium feed from the Paducah GDP. Only Oak Ridge and PORTS produced HEU products. Therefore, it is reasonable to assume that the list of contaminants and their relative magnitudes would be comparable. In addition to radioisotopes, both facilities had full-service converter repair and cleaning facilities that used TCE as the primary solvent. Both plants had uranium recovery and general maintenance facilities.

There has been significant progress with D&D of ETTP, including the demolition of numerous facilities directly applicable to understanding the potential waste volume and characteristics of the waste to be generated at PORTS. For the ETTP facilities, characterization of the final regulatory waste type was completed prior to commencement of D&D but after a demolition decision was made.

Characterization of the ETTP buildings and structures is similar to the characterization ongoing and planned for PORTS buildings and structures. The purposes for characterization at ETTP include determining the appropriate waste handling and disposal approach as well as compliance with health and safety procedures and environmental requirements including all ARARs. To provide some understanding of the types and level of contamination that may be found in waste streams generated from demolition of the process buildings and maintenance facilities at PORTS (RC-1), the waste characterization data collected in similar ETTP buildings were considered. The data reported in this section were used specifically to determine if the waste could be disposed on the DOE reservation in Oak Ridge and therefore, the level of quality required was high.

At ETTP, potentially radiologically contaminated structures are surveyed. The major waste streams (roofs, concrete, structural steel and sidings) are also characterized using random sampling protocol developed following the Multi-Agency Radiation Survey and Site Investigation Manual approach. Biased samples are collected, when appropriate, based on historical use or release information, radiological survey results, or facility walkdowns prior to demolition. Sampling techniques and analytical processes and protocols established by EPA for the specific media are used. These include EPA-approved collection methods using core drilling for concrete, roofs, siding; saws for coupons for metal radiological samples; drill cuttings or shavings for metal chemical samples; wipe samples for dust or removable radioactivity; and grab samples for loose bulk media. Sample transport and analysis are managed by a Sample Management Office that uses only DOE Laboratory Accreditation Program-approved laboratories. These organizations follow nationally recognized protocols for chain of custody, quality (blanks, splits, and duplicates), contaminate analysis, and validation of data (typically 10 percent at a Level III validation). Radioisotopic analysis is primarily by alpha spectroscopy, though technetium-99 is analyzed by liquid scintillation. Chemical contaminant analysis is most typically by Test Methods for Evaluating Solid Waste, Physical/Chemical Methods (SW-846), Method 6010B for metals, Method 8270C for SVOCs, and Method 8082 for PCBs. TCLP analysis follows EPA 1311.

The K-1401 Building at ETTP was a maintenance facility serving the entire ETTP site through most of its active mission life. The K-1401 Building equivalent at PORTS is the X-720 Building. The K-1401 Building was fully characterized in 2005, waste profiles were developed, and the facility was demolished with the majority of resulting waste shipped to the Oak Ridge disposal facility (Environmental Management Waste Management Facility [EMWMF]). The estimated in-place waste volume prior to demolition was approximately 47,000 cy, but the actual as-disposed volume was only 16,500 cy (BJC 2010). Table 4.3 summarizes the expected concentrations of select key contaminants in the final K-1401 waste, based on a considerable waste characterization sampling effort.

Table 4.3. Summary of K-1401 Key Site-related Contaminant Concentrations

Site-Related Contaminant	Expected Concentration E(X)[a]
Technetium-99	13.94 pCi/g
Uranium-233/234	17.80 pCi/g
Uranium-235	1.36 pCi/g
Uranium-238	16.72 pCi/g
Chromium[b]	308.02 mg/kg
Lead[b]	363.50 mg/kg
PCB-1254[c]	58.35 mg/kg
PCB-1260[c]	8.72 mg/kg

[a] Source: BJC 2006
[b] Metals passed the Toxicity Characteristic Leaching Procedure test.
[c] The only Aroclors present were PCB-1254 and PCB-1260. All other PCBs were non-detects.

BJC = Bechtel Jacobs Company LLC
PCB = polychlorinated biphenyl

The K-1420 Building at ETTP was a uranium recovery facility servicing the gaseous diffusion process equipment. The K-1420 Building also performed a number of unique research and development activities with the goal of improving specific gaseous diffusion processes and/or materials used in the processes. The K-1420 Building equivalent at PORTS is the X-705 Building. The K-1420 Building was fully characterized in 2005, waste profiles were developed, and the facility was demolished with resulting waste shipped to the EMWMF. Prior to disposition, most of the equipment was removed, and yellow cake and other nuclear materials were segregated and disposed separately. The estimated in-place waste volume prior to demolition was approximately 8,300 cy, but the actual as-disposed volume was only 3,600 cy (BJC 2010). Table 4.4 summarizes the expected concentrations of select key contaminants in the final K-1420 structural waste.

Table 4.4. Summary of K-1420 Key Site-related Contaminant Concentrations

Site-related Contaminant	Expected Concentration E(X)[a]
Technetium-99	212.80 pCi/g
Uranium-233/234	273.71 pCi/g
Uranium-235	19.68 pCi/g
Uranium-238	166.94 pCi/g
Chromium	23.68 mg/kg
Lead	12.92 mg/kg
PCB-1254[b]	5.62 mg/kg

[a] Source: BJC 2005a
[b] The only Aroclor present was PCB-1254. All other PCBs were non-detects.

BJC = Bechtel Jacobs Company LLC
PCB = polychlorinated biphenyl

The K-29 Building at ETTP was a gaseous diffusion process building. The PGE and most of the other equipment was removed from the facility prior to characterization. No decontamination of the K-29 Building was performed prior to D&D. The K-29 Building is essentially equivalent to the top end of the X-330 Building at PORTS. It was fully characterized in 2005, waste profiles were developed, and the facility was demolished with the resulting waste shipped to the EMWMF. The estimated in-place waste volume prior to demolition was approximately 32,000 cy, and the actual as-disposed volume was 25,000 cy (BJC 2005b). Table 4.5 summarizes the expected concentrations of select key contaminants in the final K-29 Building structural waste.

Table 4.5. Summary of K-29 Key Site-related Contaminant Concentrations

Site-related Contaminant	Expected Concentration E(X)[a]
Technetium-99	299.80 pCi/g
Uranium-233/234	84.40 pCi/g
Uranium-235	4.58 pCi/g
Uranium-238	19.93 pCi/g
Chromium[b]	274.73 mg/kg
Lead[b]	610.77 mg/kg
PCB-1254[c]	4.54 mg/kg
PCB-1260[c]	3.36 mg/kg

[a] Source: BJC 2005b
[b] Metals passed the Toxicity Characteristic Leaching Procedure test.
[c] The only Aroclors present were PCB-1254 and PCB-1260. All other PCBs were non-detects.

BJC = Bechtel Jacobs Company LLC
PCB = polychlorinated biphenyl

4.2.3 PORTS Non-D&D Waste (RC-2) Contaminants Summary

Information from PORTS-specific environmental management documentation is used to assess the types of contaminants that may be present in non-D&D waste (RC-2) streams generated from environmental restoration activities conducted outside the DFF&O. The *Methods for Conducting Human Health Risk Assessments and Risk Evaluations at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2013a) developed tables for COPCs for radioisotopes, organics, and inorganic contaminants. These contaminants originated from the buildings and associated operations on PORTS, and although the releases may have been historic, they are possibly still present in the buildings or equipment. Table 4.6 provides a summary of radioisotopes considered as PORTS-related contaminants.

Table 4.6. PORTS Radionuclide Site-related Contaminants

Americium-241	Technetium-99
Neptunium-237	Uranium-234
Neptunium-237 (+D)	Uranium-235 (+D)
Plutonium-238	Uranium-238
Plutonium-239	Uranium-238 (+D)
Plutonium-240	

+D = plus daughter products

Table 4.7 provides a summary of organic constituents considered as PORTS-related contaminants. Table 4.8 provides a summary of inorganic constituents considered as PORTS-related contaminants.

Table 4.7. PORTS Organic Site-related Contaminants

Acetone	Dichlorodifluoromethane	Kepone (Chlordecone)
Acetonitrile	Dichloroethane, 1,1-	Lindane (gamma-HCH)
Acrylonitrile	Dichloroethane, 1, 2-	Methoxychlor
Aldrin	Dichloroethylene, 1,1-	Methyl Bromide (Bromomethane)
Benzene	Dichloroethylene, 1,2-	Methyl Isobutyl Ketone (Methyl-2-pentanone, 4-)
Bis(2-ethylhexyl)phthalate	Dichloroethylene, 1,2-cis	Methylene chloride
Bromodichloromethane	Dichloroethylene, 1,2-trans	Nitrobenzene
Bromoform	Dieldrin	Nitroso-di-N-propylamine, N-
Butadiene, 1,3-	Dinitrotoluene, 2,4-	cPAHs[a]
Butanone, 2-	Dioxane, 1, 4-	Noncarcinogenic PAHs[b]
Carbon disulfide	Dioxins/Furans[c]	PCBs[d]
Carbon Tetrachloride	Endosulfan	Styrene
Chlordane	Endosulfan sulfate	Tetrachloroethane, 1,1,1,2-
Chlorobenzene	Endrin	Tetrachloroethane, 1,1,2,2-
Chloroethane	Ethylbenzene	Tetrachlorethylene
Chloroform	Heptachlor	Toluene
Chloromethane (methyl chloride)	Heptachlor epoxide	Trichlorobenzene,1,2,4-
Chlorophenol, 2-	Hexachlorobenzene	Trichloroethane, 1,1,1-
Cresol, p-	Hexachlorobutadiene	Trichloroethane, 1,1,2-
DDT, total[e]	Hexachlorocylcohexane, Alpha- (alpha-HCH)	Trichloroethene
Dibenzofuran	Hexachlorocylcohexane, Beta- (beta-HCH)	Trichloropropane, 1,2,3-
Dibromochloromethane	Hexachlorocylcohexane, Delta- (delta-HCH)	Vinyl chloride
Dibromo-3-chloropropane, 1,2-	Hexanone, 2-	Xylenes, Mixture
Dichlorobenzene	Isobutyl alcohol	

[a] Carcinogenic PAHs: benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene.
[b] Noncarcinogenic PAHs: acenaphthene, anthracene, benzo[g,h,i]perylene, fluorene, fluoranthene, naphthalene, 2-methylnaphthalene, and pyrene.
[c] Dioxins/furans include dioxin-like chemicals.
[d] PCBs include total PCBs and/or Aroclors.
[e] Total DDT includes 4,4’-DDT, 4,4’-DDD, 4,4’-DDE, 2,4’-DDT, 2,4’-DDD, and 2,4’-DDE.

cPAH = carcinogenic polycyclic aromatic hydrocarbon
PAH = polycyclic aromatic hydrocarbon
PCB = polychlorinated biphenyl

Table 4.8. PORTS Inorganic Site-related Contaminants

Aluminum	Total Chromium	Mercury
Antimony	Cobalt	Nickel
Arsenic	Copper	Selenium
Barium	Cyanide	Silver
Beryllium	Fluoride	Thallium
Cadmium	Iron	Uranium
Chromium (III)	Lead	Vanadium
Chromium (VI)	Manganese	Zinc

4.2.4 Summary of Waste Characterization and Assumptions

The following represent some important points summarizing known process knowledge and available characterization data. These points are highlighted as significant to the development and evaluation of remedial action alternatives:

- In excess of 95 percent of the remaining non-containerized radioactive material inventory associated with the GDP is contained within the PGE in the three main process buildings. This PGE waste stream represents approximately 19 percent of the total D&D waste (RC-1) volume.

- The major isotopes of uranium and technetium-99 are the most significant COPCs and potential contributors to risk.

- The residual radioactive material present in the PGE in the X-326 Building contains the highest activity concentrations of technetium-99 and uranium-235 present at the GDP. Sampling results and process history support the presence of nonuniformly distributed pockets of residual materials within the PGE in X-326.

- The X-333 Building contains up to an order of magnitude lower activity concentrations of technetium-99 within the residual radioactive materials present in the PGE.

- There is an extensive list of PORTS-specific contaminants that may be present in the waste streams (RC-2) or potential on-PORTS fill areas (RC-2, RC-3) as described in Section 4.1.2, including radiological, organic, and inorganic constituents. Soil sampling data from the vicinity of the GDP indicate that many of these same contaminants are present in the environmental media immediately surrounding buildings.

4.3 VOLUME AND CHARACTERISTIC UNCERTAINTY

There are uncertainties associated with the volume estimates presented in Section 4.1. The larger buildings have been the focus of significant efforts in estimating their waste volumes by using building drawings and engineering take-offs, supplemented by facility walkdowns where physical measurements were most often taken. The more numerous smaller building volume estimates were most often derived from parametric models or tools using factors such as facility footprint, number of stories, and general facility purpose. Even with great attention to detail and precision, estimated waste volumes can be high or low by a factor of 2 or 3 because of assumptions regarding interior wall construction, void spaces, and the presence or absence of miscellaneous materials. The waste volume estimate of a building prior to D&D is called an in situ or in-place estimate. Waste volume estimates for waste generated under the Ohio Consent Decree (RC-2) are also uncertain because there are uncertainties relative to depth and breadth of contamination; assumptions regarding whether excavation is needed and the excavation approach, side-slopes, etc.; and final cleanup levels. Waste volume estimates for in situ soils are also often described as “bank” estimates.

Concrete, metals, and other miscellaneous building materials typically expand during demolition activities, as does soil. The expanded waste estimate is referred to as the “as-generated” waste volume estimate. The as-generated volume estimate is necessary to plan and estimate waste transportation activities, storage/staging footprint considerations, etc. Experience on similar D&D projects in Oak Ridge suggests that 10 to 12 cy of as-generated waste is shipped in each dump truck with a rated capacity of 18 cy.

The final state-of-waste is the “as-disposed” waste volume estimate. DOE and commercial disposal facilities carefully track use of disposal air space as this measurement represents the most accurate volume capacity of a disposal facility. As waste is placed in a disposal facility, it is compacted in lifts. Soil waste or clean fill is used to properly dispose of waste forms with void spaces (EC-2). Compaction of waste is necessary to mitigate void spaces and the risk of future unacceptable landfill subsidence. The EMWMF in Oak Ridge tracks the as-disposed volume using quarterly surveys and documents the results in the annual EMWMF Capacity Assurance Remedial Action Report. The estimates of as-disposed waste disposed at EMWMF have consistently been less than the in situ or in-place estimate, and in some cases have been significantly lower. Table 4.9 illustrates this point for the three large ETTP buildings, one of which is a gaseous diffusion process building. The estimate for K-29 was only for the building structure and non-PGE systems as all PGE had been removed under a separate contract. The K-1401 and K-1420 facilities were full of contaminated equipment and miscellaneous waste as waste volume estimates were developed. The equivalent PORTS buildings are listed.

Table 4.9. Benchmarking Historical ETTP In-place Volume Estimates

Building (PORTS Equivalent)	Original Estimate (cy)	Final Estimate (cy)
K-1401 (X-720)	47,000	16,500
K-1420 (X-705)	8,300	3,600
K-29 shell (top end of X-330)	32,000	25,000

Source: BJC 2010

BJC = Bechtel Jacobs Company LLC
PORTS = Portsmouth Gaseous Diffusion Plant

Similar processes for estimating the initial waste volumes were used at both PORTS and ETTP. This background suggests that the PORTS waste estimates may be high, but these data are not sufficiently robust to make that judgment. Even if each building waste volume estimate is high, there may be generation of incidental wastes that have not been considered (such as some utilities or subsurface structures), and these wastes would bring the total waste stream volumes to higher levels.

There are uncertainties associated with the characteristics of the waste. However, the uncertainties are bounded by process knowledge and information available from the demolition of ETTP. The characteristics of the types of waste streams are well understood to allow a complete evaluation of disposal alternatives.

Despite these disparities, the overall conclusions as to which buildings are the major contributors to waste volumes (X-326, X-330, and X-333), the order of magnitude of the waste volumes (1.47 to 2.18 million cy), and what waste forms may be generated are sufficient to support development and evaluation of waste disposition remedial alternatives.

4.4 WASTE VOLUME SUMMARY

Table 4.10 presents a summary of the D&D waste volumes (RC-1) by waste form used through the FS portion of the document (Sections 7 through 9). The groups of waste are based on the potential action. The residual soil (RC-1, EC-1) is separated because it has fill properties and is used differently during disposal operations. There are also different costs associated with disposing of soil (EC-1) versus non-soil waste (EC-2) off Site. The PGE is separated because of the additional handling that is required (primarily covered in the process buildings RI/FS) and the specialized transportation requirements and costs if the equipment is moved whole. Targeted recyclables are separated because they would be moved to a recycling operation instead of being sent to a disposal facility. The rest of the material will be considered together in the FS.

Table 4.10. D&D Waste (RC-1) Disposition Volumes

D&D Waste Form Description[a]	In Situ Volume (cy)
Residual Soil (EC-1)	53,000
Asbestos (EC-2)	3,000
Concrete (EC-2)	400,000
Other Building Waste (EC-2)	629,000
Process Gas Equipment (EC-2)	272,000
Targeted Recyclables (EC-2)	110,000
Total D&D Waste and Recyclables (RC-1)	**1,467,000**

[a] Includes DFF&O buildings and structures/infrastructure with contents, equipment, and soil.

D&D = decontamination and decommissioning
DFF&O = *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto*
EC = engineering category
RC = regulatory category

HIGHLIGHTS OF SECTION 4

- A volume of 1.47 million cy of D&D waste (RC-1) is evaluated in the RI/FS.
- The majority of the D&D waste (RC-1) volume (75 percent) is generated from D&D of the three process buildings.
- Most D&D waste (RC-1) is classified as LLW, although there are some smaller volume streams controlled by other regulations such as RCRA and TSCA.
- The primary contaminants in the D&D waste (RC-1) are radionuclides. Metals, VOCs, SVOCs, PCBs, and radionuclides are present in contaminated media (RC-1, EC-1 and RC-2).
- Based on ETTP data, large volumes of waste with lower concentrations of contaminants are anticipated to be generated. Recently collected deposit data from the PORTS PGE show small volume streams with higher levels of contamination are likely.
- Up to an estimated 710,000 cy of additional non-D&D waste (RC-2) may be generated from non-DFF&O remediation efforts at PORTS.

NEXT STEP: SECTION 5 PUTS TOGETHER THE COMPONENTS OF THE CSM AND ASSESSES THE THREAT, THEREBY COMPLETING THE PROBLEM DEFINITION

This page is intentionally left blank.

5. POTENTIAL THREAT TO HUMAN HEALTH, SAFETY, AND THE ENVIRONMENT

Section 5 presents a streamlined evaluation of the potential threat to human health, safety, and the environment from the no-action condition in which the buildings and structures at PORTS would eventually degrade and no waste disposition would occur, resulting in releases of contaminants with migration to locations where exposures to human and ecological receptors may occur. This section uses the sources, migration pathways, and potential receptors described in previous sections to develop a CSM to understand the potential threats to human health and the environment. The potential threat analysis is streamlined because only a comprehensive qualitative analysis of risks to human health and ecological receptors is presented as agreed upon in the DFF&O. This qualitative evaluation of potential threats to human health and the environment is based on the no-action conditions under which the former GDP buildings and structures at PORTS are assumed to no longer undergo surveillance and maintenance (S&M), existing security and institutional controls are eliminated, and the resultant condition is that the buildings degrade and ultimately release currently contained contamination.

This streamlined evaluation follows PORTS-specific risk guidance for conducting both human health and ecological risk assessments. The human health evaluation is based on the *Methods for Conducting Human Health Risk Assessments and Risk Evaluations at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2013a). The ecological evaluation is based on the *Methods for Conducting Ecological Risk Assessments and Ecological Risk Evaluations at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2013c).

The potential threat to human health is assessed comprehensively, but qualitatively, in Section 5.1. The potential effects to ecological species are addressed qualitatively in Section 5.2. On the basis of the evaluations presented in this section, the no-action alternative is shown to present an unacceptable level of risk to human and ecological receptors. On the basis of this unacceptable level of risk, remedial actions are warranted.

5.1 POTENTIAL THREAT TO HUMAN HEALTH

A streamlined evaluation of risk to human health for the no-action condition was conducted for purposes of determining whether remedial actions are warranted and to establish a risk analysis in support of developing and evaluating alternatives. To support the presentation of this risk evaluation, a previously established segmentation of PORTS, termed “quadrants,” was employed. Four quadrants were previously defined for purposes of conducting historical environmental cleanup activities at PORTS. These four quadrants encompass all areas on the PORTS reservation. Evaluating the potential threat to human health using this quadrant approach permits the risk evaluation to consider unique building conditions and hazardous material inventories in the buildings within each quadrant and the likelihood of these buildings to contribute additional contaminant mass to the exposure locations within each quadrant. Relating the known conditions within the buildings to the relevant environmental data provides information on not only the release potential of the remaining hazardous materials in the buildings, but also on the relative movement of many of these same materials, in the form of contaminants, in the environment as a result of historical spill and release events.

Using the intent of the four-step process outlined in the PORTS-specific risk assessment guidance (DOE 2013a), the qualitative human health risk evaluation identifies COPCs by using previous investigations and process knowledge. It develops a CSM that identifies the source(s) of the COPCs, their likely migration pathways and potential exposure routes, and their ultimate fate in the environment. Finally, using the transport and fate information along with toxicity information, the COCs are identified for applicable potential receptors. The PORTS-specific guidance focuses primarily on quantitative risk assessments. The qualitative risk assessment for this RI/FS uses the same steps, but each step is conducted on the basis of process knowledge instead of contaminant-specific data. For instance, the potential COPC identifications are based on operations that occurred in the various buildings or on environmental data associated with past releases from the buildings. They are not based on a screening of building analytical data against Type 2 screening levels and background levels. Likewise, the final identification of COCs and potential exposure pathways of concern are based on process knowledge about the prevalence of contamination sources and their likelihood to release, as well as their fate in the environment. In summary, risk is characterized in this analysis by qualitatively integrating process information and toxicity information about the contaminants likely to be present with exposure information for hypothetical receptors.

This streamlined assessment evaluates the risk from not disposing of waste, which is the no-action alternative. Under the no-action alternative, no D&D, S&M activities, or institutional control measures are assumed to have been conducted, and the equipment, buildings, and structures would hypothetically continue to deteriorate over time. The resulting waste from structural failure would lay where it falls, and uncontrolled release of contaminants from within the structures and equipment to the environment would eventually occur because no permanent disposal decision is made under the assumed no-action alternative. Natural structural degradation is a slow process characterized by incremental degradation of structural components eventually leading to episodic collapse. Therefore, persons in and around the deteriorating buildings would be at risk of injury from physical hazards such as being struck by falling structural components or collapse of floors resulting in falls.

5.1.1 Contaminant Identification

COPCs are those contaminants that are suspected to be associated with PORTS operations and could have a detrimental impact on human health if exposure occurs. For this qualitative assessment, the identification of COPCs for human health results in the same COPCs for ecological receptors. These COPCs represent the contamination found across PORTS. First, a list of contaminants identified in earlier investigations during the RFIs in potentially contaminated areas at PORTS was obtained and evaluated. (These data differ from the data collected during this RI, which were collected in support of siting a potential OSDC.) While this waste disposition RI/FS does not focus on environmental media, the earlier investigations illustrate what has been released to the environment historically. Even if these contaminants were identified in soil, they likely represent releases from activities that occurred originally in or around the buildings or as a result of waste generated in or around the buildings. Because evaluation of the risks from environmental contamination will be completed in the future, the data summary tables from the earlier RFIs were used as they were originally presented.

Then COPCs for this evaluation are identified by considering the history and operations that occurred in the major buildings in each PORTS quadrant and by identifying chemicals or radionuclides that are still likely to be present in enough mass to potentially release and be a threat to human health in the future. A map delineating the quadrants and the flow of groundwater is presented in Figure 5.1. Historical uses of chemicals that are no longer present may present a risk from exposure to environmental media, but they would not be a future risk from a release at a degrading building and, therefore, would not be identified as COPCs for purposes of this RI/FS. The COPCs associated with the PORTS process buildings, complex facilities, and other support facilities are identified by quadrant below. Section 4.2, which discussed the characteristics of the waste streams, identifies many of these same contaminants.

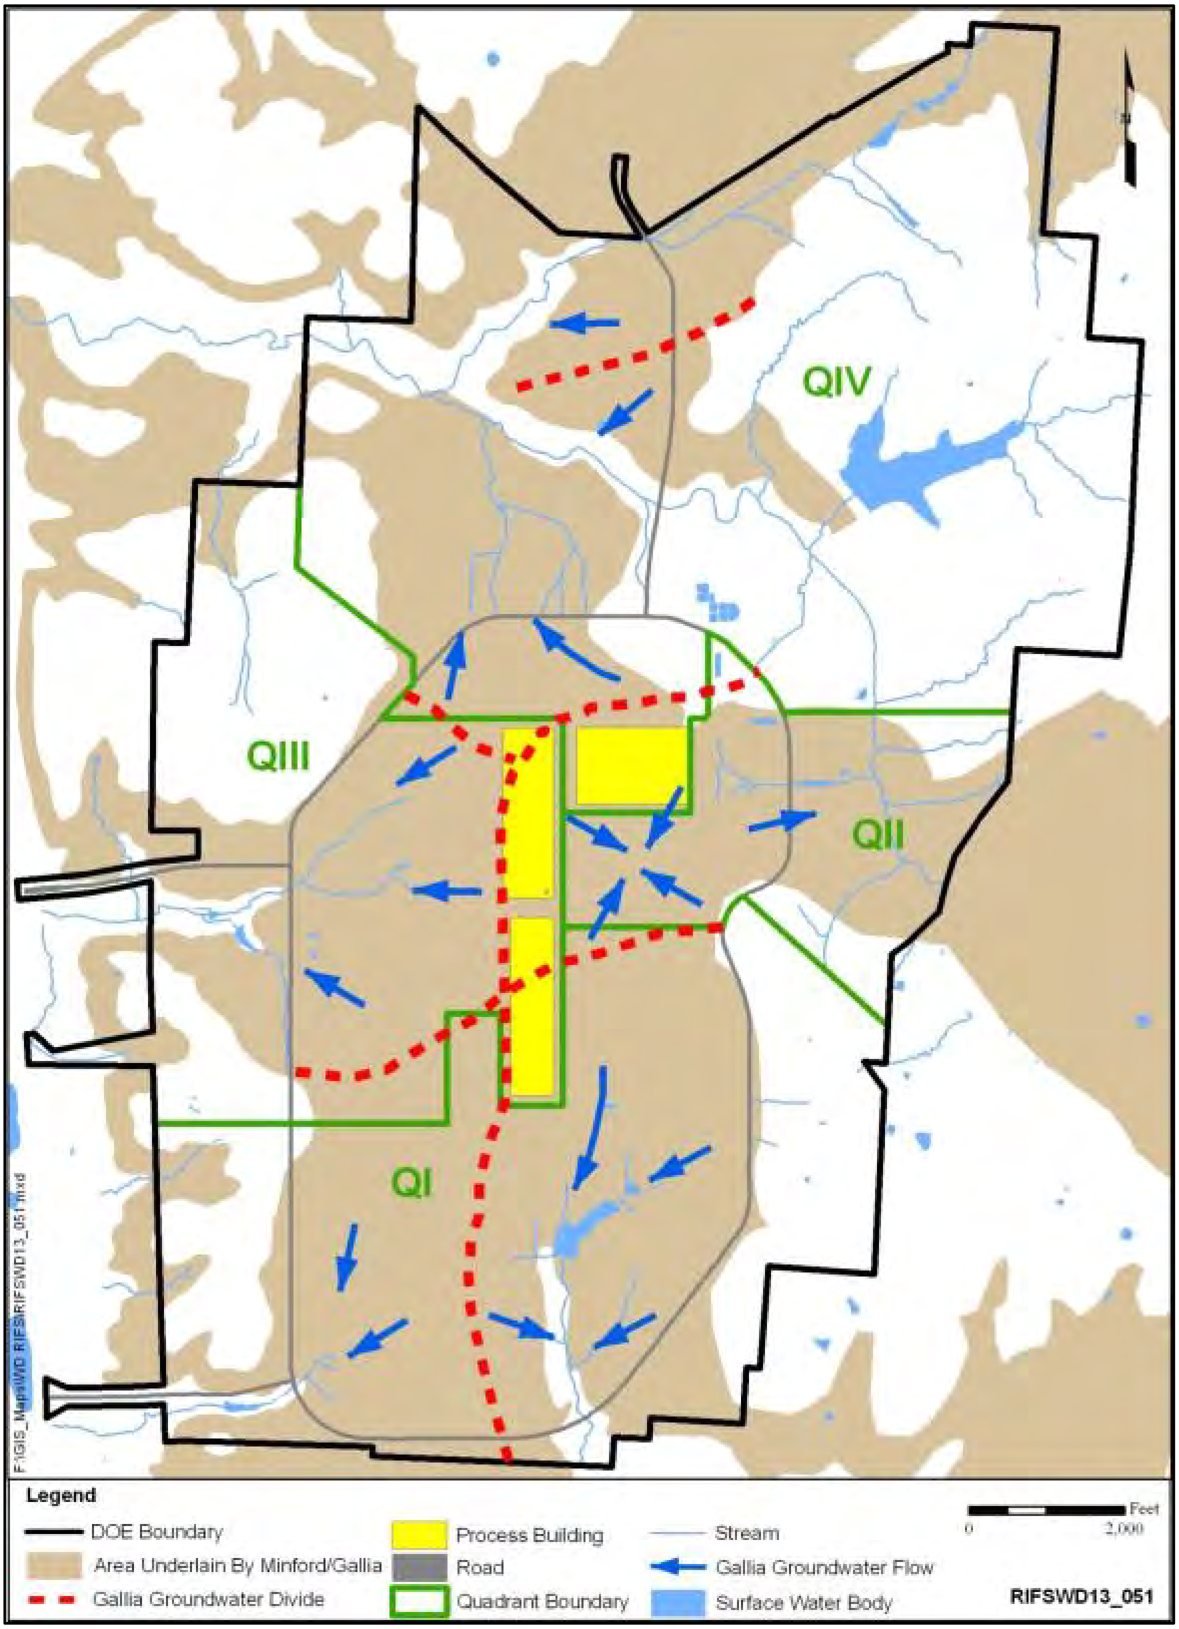

Figure 5.1. PORTS Quadrants and Groundwater Flow

Quadrant I

Several study areas, known as SWMUs were part of the RFI Quadrant I report (DOE 1996a), including the X-104A Indoor Firing Range, X-600A/X-621 Coal Storage Yard and Coal-Pile Runoff, X-230K South Holding Pond, X-710/X-710A Technical Services Building and Neutralization Pit, and Peter Kiewit Landfill. Table 5.1 provides a list of contaminants detected in environmental media that were either detected in more than 10 percent of the samples or detected in several media. For example, Aroclor-1260 is detected in both soil media (0 to 2 ft and 0 to 10 ft) and surface water (most notably in the Peter Kiewit Landfill SWMU), but not necessarily in more than 10 percent of the samples, so it is included on the list. Every chemical was not sampled in every medium. For example, Aroclor-1260 was not sampled in groundwater, and analysis for isotopic uranium was not performed. Depending on the media and how the data were summarized in the RFI report, some results are presented as a range of detected concentrations and others are presented as the 95th percentile upper confidence limit (UCL95) on the mean. The summary tables are as presented in the RFIs; no additional evaluation on the data was performed.

Table 5.1. Quadrant I Contaminant Concentrations by Media for PORTS

Media	Chemical	Units	Frequency of Detection	Range of Detected Concentrations
Soil (0-2 ft)				
	Aroclor-1254	μg/kg	2/52	180-740
	Aroclor-1260	μg/kg	8/52	23-760
	TCE	μg/kg	2/57	6.90-19
	Arsenic	mg/kg	52/55	1.30-37
	Barium	mg/kg	54/54	28-150
	Chromium	mg/kg	70/70	4.40-240
	Lead	mg/kg	54/54	6.70-450
	Mercury	mg/kg	47/55	0.01-0.09
	Silver	mg/kg	15/54	2.10-14
	Technetium	pCi/g	10/45	200-2,587,900
	Uranium, Total	mg/kg	45/45	1.9-154
Soil (0-10 ft)				
	Aroclor-1254	μg/kg	5/146	10-740
	Aroclor-1260	μg/kg	13/146	23-460,000
	TCE	μg/kg	2/175	2.50-3.30
	Arsenic	mg/kg	139/145	1.30-41
	Barium	mg/kg	140/140	20-250
	Chromium	mg/kg	197/199	3.60-240
	Lead	mg/kg	140/140	4.50-450
	Mercury	mg/kg	109/141	0.01-0.39
	Silver	mg/kg	56/140	1.50-110
	Technetium	pCi/g	17/145	200-2,587,900
	Uranium, Total	mg/kg	145/145	1.70-154
Sediment				
	Fluoranthene	μg/kg	5/6	24-560
	Arsenic	mg/kg	10/10	9.20-20
	Barium	mg/kg	10/10	30-92
	Chromium	mg/kg	9/10	6.30-22
	Lead	mg/kg	10/10	12-230
	Manganese	mg/kg	6/6	14-540
	Mercury	mg/kg	10/10	0.02-0.09

Table 5.1. Quadrant I Contaminant Concentrations by Media for PORTS (Continued)

Media	Chemical	Units	Frequency of Detection	Range of Detected Concentrations
Sediment				
	Nickel	mg/kg	5/6	18-870
	Silver	mg/kg	7/10	4.30-9.90

	Zinc	µg/L	11/13	90.79

[a] Max detect (mean = 4.65) Peter Kiewit Landfill data.

TCE = trichloroethene
UCL95 = 95th upper confidence limit on the mean

The facilities in this quadrant with the highest potential for exposure of receptors to contamination are located in the X-710 Complex, which is composed of the following buildings:

- X-710 Technical Service Building
- X-710A Gas Manifold Shed
- X-710B Explosion Test Facility.

The buildings in the X-710 Complex contain laboratories that provided technical, production, and development support for the Portsmouth GDP. Operations included material sampling and testing, chemical analysis and laboratory services, and housing for high pressure gas manifolds and cylinders of gas for use in laboratory functions. In addition, the X-710B Explosion Test Facility conducted experiments involving unstable compounds. Environmental releases have occurred as discharges from laboratory sinks and floor drains in the X-710 Technical Service Building. These discharges flow into the X-710 Neutralization Pit, which then discharges to the sanitary sewer. Prior to 1985, solvent wastes were discarded down laboratory sinks. The X-710 facility is suspected of being a potential source for a TCE plume near the building. Known releases of contaminants within the Technical Service Building include 2,000 gal of RCW, mercury spills from diffusion pumps on the mass spectrophotometer, and “smoking” sample U-tubes from connecting or disconnecting the containers to the spectrophotometer. Equipment used to analyze PCBs is contaminated. Hazards associated with the building include organic solvents, heavy metals, and mixed wastes, and lead-based paint is suspected to be present on the walls and piping of the facility. ACMs are in the thermal system insulation around pipes, floor tiles, and steam condensate lines (DOE 1993).

As a result of evaluating the processes and history of the buildings and comparing the list of contaminants that may still be present to the contaminants that have historically shown to release and migrate in the environmental media, COPCs in this quadrant include the following:

- Uranium (uranium-234, uranium-235, and uranium-238)
- Total uranium
- Technetium-99
- VOCs (e.g., TCE)
- SVOCs
- PCBs
- Cyanides
- ACMs
- Lead
- Mercury
- Chromates.

Asbestos (i.e., ACM) was not sampled in the environmental media and is currently managed under an S&M program at PORTS.

Quadrant II

Some of the Quadrant II SWMUs identified during the RFI (DOE 1996b) included the X-700 Chemical Cleaning Facility, X-705 Decontamination Building, X-720/X-720NP Maintenance Building and Neutralization Pit, East Drainage Ditch, and Little Beaver Creek. Contaminants frequently detected in environmental media (more than 10 percent of the time) in this quadrant are presented in Table 5.2. In this table, a UCL95 is presented (instead of a concentration range) for all media except groundwater, which is presented as a mean and maximum concentration.

Table 5.2. Quadrant II Contaminant Concentrations by Media for PORTS

Media	Chemical	Units	Frequency of Detection	UCL95
Soil (0-2 ft)				
	Acenaphthene	μg/kg	22/72	316.20
	Anthracene	μg/kg	31/72	423.79

The buildings in this quadrant with the highest potential for exposure of receptors to contamination are located in the X-700 Complex, X-705 Complex, and X-720 Complex, which are composed of the following buildings:

X-700 Complex

- X-700 Converter Shop and Cleaning Building
- X-700A Air Conditioning Equipment Building
- X-721 Radiation Instrumentation Calibration (RADCAL) Facility.

The X-700 Complex buildings were used for equipment maintenance support involving nonradioactive or low-level radioactive contaminated equipment from the diffusion cascade. In addition, they provided chemical cleaning operations, an air conditioning equipment building, and an instrument calibration facility to test radiation instruments.

The X-700 Converter Shop and Cleaning Building is a steel-framed, high-bay building with transite siding and concrete floors. The facility was used for equipment maintenance support involving non-radioactive or low-level radioactively contaminated equipment from the diffusion cascade. The building includes areas for chemical cleaning, converter disassembly/assembly, and welding. It also includes the X-721 RADCAL Facility. The RADCAL Facility houses several high-intensity radiation sources, which are intrinsically safe or are used remotely inside a shielded radiation room. A gamma irradiator and one filtered 320 kV constant potential X-ray unit are located in the “beam room” at fixed positions.

X-705 Complex

- X-705 Decontamination Building
- X-705D Heat Booster Pump Building
- X-705E Oxide Conversion Area.

The X-705 Complex consists of three buildings and/or structures, with X-705E located inside of X-705. The X-705 Decontamination Building was used for PGE disassembly and decontamination, uranium recovery, and routine chemical analysis. Disassembly and decontamination of PGE resulted in X-705 being exposed to the same radioactive contaminants as the process buildings. The entire building, except for the laundry, laboratory, break room, lockers, and offices located in the southeastern part of the building, is a contamination control zone because of radiological contamination (TPMC 2006c). Radiological contamination has become fixed in the floors, in walls, and on the inside surfaces of the building and its fixed equipment, including the washing equipment. Removable contamination is also present.

Because PGE contaminated with technetium-99 has been disassembled and decontaminated in X-705, technetium-99 contamination is also present. Decontamination actions involved cleaning and disposing small quantities of transuranic elements. The transuranic elements tended to stay behind in cylinder heels after feeding. Uranium and technetium are the two main radioactive materials present in X-705, and detectable concentrations of transuranic elements and uranium daughter products are also present in the building.

The X-705E Oxide Conversion Area was operated from 1967 until 1978 and was used to convert uranium oxide containing technetium-99 and transuranic elements to UF_6 for feed to the enrichment cascade. It is highly contaminated radiologically. The area is posted as a contamination control zone and is sealed because of potential or suspected contamination from transuranics. The equipment was shut down in 1978 because of high airborne radiation readings in the facility.

The X-705D facility served to circulate RCW through X-705 for heating. Its use was discontinued in 2001 when the gaseous diffusion cascade was shut down.

X-720 Complex

- X-720 Maintenance and Stores Building
- X-720B Radio Base Station
- X-720C Paint and Storage Building.

The X-720 Complex consists of three buildings. The X-720 Maintenance and Stores Building provided shop support, which involved sheet metal, utility and process maintenance, electrical, instruments, valves, compressors, spectrometers, and refrigeration. Outside the building are two 1,000-gal trichloroethane tanks and gasoline tanks. The abandoned X-720 Neutralization Pit, also located outside, was used from 1954 to 1991 to neutralize acidic and metal-bearing wastewaters before discharge to the sanitary sewer. This pit was partially removed in November 1998; all that remains is the bottom and the west wall, which were left in place due to constraints imposed by the tank's proximity to the X-720 building foundation. The X-720B Radio Base Station was used to store and maintain communications equipment, and X-720C was used for general storage, including storage of a variety of paints and solvents. Surface-wipe samples within the X-720 Maintenance and Stores Building were analyzed for beryllium and had results exceeding the DOE 10 *CFR* 850 release criterion.

By comparing the potential for residual contamination in the buildings to contaminants that have historically released in this quadrant, the following COPCs from these buildings were identified:

- Uranium (uranium-234, uranium-235, and uranium-238)
- Total uranium
- Technetium-99
- Neptunium-237
- Plutonium-239
- VOCs (e.g., TCE)
- PAHs
- PCBs
- Freon-502, Freon-22
- ACMs
- Arsenic
- Beryllium
- Cadmium
- Chromates
- Lead
- Mercury
- Nickel
- Titanium
- Zinc.

Process lines from X-700, X-701C, and X-705 discharged to the former X-701B Holding Pond, which is a source for a TCE plume.

Quadrant III

Some of the SWMUs identified in the Quadrant III RFI (DOE 1996c) included the X-326/X-330 Process Buildings, X-616 Liquid Effluent Control Facility/Former Chromium Sludge Lagoons, and X-6619 Sewage Treatment Facility. Contaminants detected in environmental media (more than 10 percent of the time) in this quadrant are listed in Table 5.3.

Table 5.3. Quadrant III Contaminant Concentrations by Media for PORTS

Media	Chemical	Units	Frequency of Detection	Range of Detected Concentrations
Soil (0-2 ft)

[a] Technetium-99 was not analyzed for in groundwater.

TCE = trichloroethene

The buildings in Quadrant III with the highest potential for exposure of receptors to contamination are two process buildings (X-326 and X-330). The primary radiological COCs within the process buildings are uranium (including the uranium isotopes uranium-234, uranium-235, and uranium-238) and technetium-99. As discussed in Section 4.2.1.1, radionuclides introduced into the gaseous diffusion system from the processing of reactor returns were typically generated through the PUREX process. The PUREX process separated uranium and plutonium from spent nuclear fuel. The byproduct of this process was UO_3, which was returned to the uranium feed cycle for the production of UF_6 feed materials. The feed material produced from this process was called “reactor returns.” Although the PUREX process was relatively efficient in removing fission products and transuranic elements from the uranium, measurable amounts of technetium-99, neptunium-237, and plutonium-239 remained with the uranium feed material and were introduced into the gaseous diffusion process at PORTS.

Process equipment in the PORTS process buildings contained solid deposits of uranium compounds at the time of plant shutdown in 2001. A PORTS project was completed to reduce the size of the uranium holdup deposits to below ASM values, but some deposits remain as a primary future source of environmental contamination under no action.

Much of the introduced technetium-99 was removed from the PGE during plant upgrades in the late 1970s and early 1980s. These upgrades focused on the X-333 Building and the bottom half of the cascades in the X-330 Building. Technetium contamination remains in the X-330 equipment above the portion in which the upgrades occurred and throughout equipment in X-326, with heavier concentration of the contaminant in the side and top purge equipment.

Exterior surface uranium contamination exists in all three PORTS process buildings. Both fixed and removable contamination can be found on the operating and cell floors in X-326 and X-330. Surface technetium-99 contamination can be found primarily in the southern portion of the upper floor in the X-326 Building. This location is in the vicinity of the purge cascades.

Chemical trapping materials in the process buildings include alumina, such as Al_2O_3 and NaF. These trapping materials contain elevated concentrations of uranium, HF, technetium-99, and heavy metals.

Asbestos is found throughout the buildings on piping, in equipment housings, and in the transite paneling on the exteriors of buildings. PCBs from electrical capacitors, transformers, and impregnated ventilation gaskets; metals such as lead and silver solder from tubing fittings and other applications; cadmium and other metals from alloys and trapping materials; strong oxidizing agents from the residual UF_6, fluorine, and HF are anticipated to be present.

Chemical hazards in the process buildings include coolant (R-114) that was used as the primary process coolant for the UF_6 gas. Residual amounts of the coolant may be present in coolant tanks or piping in the process buildings. A small amount of liquid coolant (fluorinated and/or chlorinated carbon compounds) may be found in the tails area of the X-330 Building. The compound Miller's Fluorinating Lubricant may be found in the cold recovery systems in X-330 and X-333. RCW was used as the secondary cooling medium to cool the R-114. Initially, the PORTS RCW treatment system contained hexavalent chromium to prevent corrosion. In the 1990s, treatment of the cooling water was changed to a more environmentally acceptable phosphate-based system. Therefore, residual chromate and phosphate compounds are anticipated in the RCW system within the three process buildings. A recent demolition project of an RCW system (X-633 cooling towers) found detected levels of residual chromates. During demolition of the X-633 RCW Complex, metals and radiological constituents were detected above PORTS PRGs in the water in the pump house wet well, valve vaults, and the pump house floor drains. Detected constituents included: cadmium, chromium, lead, and uranium-238 (DOE 2009b).

Residual amounts of PCBs are anticipated in X-326 and X-330 transformers, electrical switchgears, storage tanks, and capacitors, once PCB oils have been drained from these systems. The ventilation ducts were installed with PCB-impregnated gaskets in the duct joints as a fire retardant, because these ducts were connected to the process motors and their shaft oil lubricating systems. During normal operations and failures, lube oil from the motors leaked into the ducts, soaked through the PCB-impregnated gaskets, and dripped onto the operating floors of the process buildings. Oil collection systems constructed of polyvinyl chloride piping were installed on the ventilation duct joints to collect the PCB-laden oils. The ventilation ducts and PCB oil-collection systems are known to contain oil and radionuclide contamination.

Residual amounts of strong oxidizing agents, such as elemental fluorine and chlorine trifluoride, used in cell treatments for deposits may be encountered in surge drums, process piping, or manifolds and piping where these agents were distributed to the PGE.

Small amounts of mercury are contained in various specialized instruments essential to the proper function and operation of the PGE. For example, mercury is commonly found in temperature/pressure contact switches, chemical traps, fire pull stations, and mercury vapor lamps used for high-bay lighting (TPMC 2006c). The X-326 instrument and sampling lines contain small mercury traps that were used to remove corrosive gases within the line. These traps prevented damage to the mass spectrometer line recorders.

Arsenic may be found primarily in the X-326 Building instrument lines and sampling lines as a result of treatment gases. Beryllium is present in aluminum compressor blades and compressor impellers, and silver is present in solder joints throughout the PGE. Both are present in low parts per million quantities. Other metals such as arsenic, barium, cadmium, and lead may be found in association with the chemical trapping materials.

By comparing the potential for residual contamination in the buildings to contaminants that have historically released in this quadrant, the following COPCs from these buildings were identified:

- Uranium (uranium-234, uranium-235, and uranium-238)
- Total uranium
- Technetium-99
- Neptunium-237
- Plutonium-239
- VOCs (e.g., TCE)
- SVOCs (e.g., PAHs)
- PCBs
- ACMs
- Arsenic
- Barium
- Beryllium
- Cadmium
- Chromates (including Cr-III and Cr-VI)
- Lead
- Mercury
- Silver.

Quadrant IV

Some of the SWMUs investigated in the Quadrant IV RFI (DOE 1996d) included the X-333 Process Building, X-342 Feed Vaporization and Fluorine Generation Building, X-344A Uranium Hexafluoride Sampling Facility/Settling Tank, X-611A North, Middle, and South Lime Sludge Lagoons, and X-745B Enrichment Process Gas Yard. Similar to the results in Quadrant III, technetium was detected and considered to be a contaminant in both soil and sediments, but it was not detected in groundwater or surface water. Contaminants and their associated concentrations in the various environmental media are listed in Table 5.4.

Table 5.4. Quadrant IV Contaminant Concentrations by Media for PORTS

Media	Chemical	Units	Frequency of Detection	Range of Detected Concentrations
Soils (0-2 ft)				
	Acenaphthene	µg/kg	18/98	58-29,000
	Anthracene	µg/kg	32/98	10-91,000
	Aroclor-1260	µg/kg	8/96	26-3,800
	Benzo(a)anthracene	µg/kg	40/98	40-180,000
	Benzo(a)pyrene	µg/kg	39/98	23-85,000
	Benzo(b)fluoranthene	µg/kg	41/98	21-150,000
	Benzo(ghi)perylene	µg/kg	29/98	20-48,000
	Benzo(k)fluoranthene	µg/kg	33/98	28-62,000
	Chrysene	µg/kg	40/98	24-96,000
	Dibenz(a,h)anthracene	µg/kg	13/98	82-8,100
	Dibenzofuran	µg/kg	17/98	15-25,000
	Fluoranthene	µg/kg	63/98	8.20-660,000
	Fluorene	µg/kg	18/98	45-47,000
	Indeno(1,2,3-cd)pyrene	µg/kg	28/98	21-55,000
	Phenanthrene	µg/kg	50/98	12-500,000
	Pyrene	µg/kg	61/98	6.10-290,000
	Arsenic	mg/kg	103/103	1.50-58
	Barium	mg/kg	103/103	2.90-220
	Beryllium	mg/kg	52/103	0.61-3.90
	Chromium	mg/kg	118/119	1.30-70
	Cobalt	mg/kg	103/103	1.30-56
	Copper	mg/kg	103/103	3.20-35
	Lead	mg/kg	106/106	4.90-270
	Lithium	mg/kg	10/24	14-44
	Manganese	mg/kg	103/103	43-760
	Vanadium	mg/kg	103/103	3.80-43
	Zinc	mg/kg	117/119	9.10-480
	Technetium	pCi/g	8/109	1,100-4,400
	Uranium, Total	mg/kg	109/109	1.20-66
Soils (0-10 ft)				
	Acenaphthene	µg/kg	25/162	54-29,000
	Anthracene	µg/kg	45/162	10-91,000
	Aroclor-1260	µg/kg	12/149	22-3,800
	Benzo(a)anthracene	µg/kg	53/162	31-180,000
	Benzo(a)pyrene	µg/kg	52/162	23-85,000
	Benzo(b)fluoranthene	µg/kg	55/162	21-150,000
	Benzo(ghi)perylene	µg/kg	39/162	20-48,000
	Benzo(k)fluoranthene	µg/kg	45/162	21-62,000
	Chrysene	µg/kg	52/162	24-96,000
	Dibenz(a,h)anthracene	µg/kg	18/162	47-17,000
	Dibenzofuran	µg/kg	23/162	170-170
	Fluoranthene	µg/kg	83/162	8.20-660,000
	Fluorene	µg/kg	25/162	11-47,000
	Indeno(1,2,3-cd)pyrene	µg/kg	39/162	21-55,000
	Phenanthrene	µg/kg	67/162	12-500,000

Table 5.4. Quadrant IV Contaminant Concentrations by Media for PORTS (Continued)

Media	Chemical	Units	Frequency of Detection	Range of Detected Concentrations
Soils (0-10 ft)				
	Pyrene	μg/kg	82/162	6.10-29,0000
	Tetrachloroethene	μg/kg	20/145	1.50-71
	Arsenic	mg/kg	153/154	1.30-220
	Barium	mg/kg	155/155	2.90-500
	Beryllium	mg/kg	77/155	0.61-3.90
	Chromium	mg/kg	223/224	1.30-100
	Cobalt	mg/kg	155/155	1.30-56
	Copper	mg/kg	155/155	3.20-160
	Lithium	mg/kg	10/25	14.00-44
	Manganese	mg/kg	154/155	5.30-2,000
	Mercury	mg/kg	126/155	0.01-3.50
	Nickel	mg/kg	150/155	5.20-110
	Vanadium	mg/kg	155/155	3.80-1,300
	Zinc	mg/kg	212/224	9.10-2,100
	Technetium	pCi/g	8/195	1,100-4,400
	Uranium, Total	mg/kg	195/195	1.20-352
Sediment				
	Acenaphthene	μg/kg	14/28	15-74,000
	Acenaphthylene	μg/kg	3/28	150-960
	Anthracene	μg/kg	18/28	14-120,000
	Aroclor-1260	μg/kg	5/27	200-6,600
	Benzo(a)anthracene	μg/kg	16/28	71-180,000
	Benzo(a)pyrene	μg/kg	22/28	18-140,000
	Benzo(b)fluoranthene	μg/kg	21/28	19-140,000
	Benzo(ghi)perylene	μg/kg	16/28	61-71,000
	Benzo(k)fluoranthene	μg/kg	19/28	23-130,000
	Chrysene	μg/kg	18/28	85-190,000
	Dibenz(a,h)anthracene	μg/kg	11/28	30-17,000
	Dibenzofuran	μg/kg	11/28	8-47,000
	Fluoranthene	μg/kg	21/28	18-390,000
	Fluorene	μg/kg	13/28	15-88,000

	Fluoride	μg/L	22/26	210-830
	Zinc	μg/L	26/26	33-130

The buildings in Quadrant IV with the highest potential for exposure of receptors to contamination are the X-333 Process Building and X-300 Complex. Operations in X-333 are sufficiently similar to those in X-326 and X-330 and have a similar list of potential contaminants.

The X-300 Complex buildings are composed of the following:

- X-342A Feed Vaporization Building
- X-342B Fluorine Storage Building
- X-343 Feed Vaporization and Sampling Building
- X-344A UF_6 Sampling Facility.

The main functions of these buildings included UF_6 feed vaporization to the cascade, receipt and sampling of incoming cylinders, and sampling and shipment of product cylinders. There are documented releases of UF_6 from these buildings.

The X-342A Feed Vaporization Building was used to feed, vaporize, and sample UF_6. The high-bay area of the building originally contained 12 steam vaporizers, but the facility was shut down between 1982 and 1983. At this time, the vaporizers were replaced with two 84-in.-diameter containment autoclaves that were capable of handling UF_6 cylinders up to 48 in. in diameter for feed vaporization and liquid sampling. The autoclaves were steam-heated and designed to contain the contents of a cylinder in the event of a cylinder rupture. The two autoclaves are currently in use. The facility is currently transferring heel material from UF_6 cylinders. Fluorine production with X-342A has been discontinued. Fluorine was produced by the electrolysis of HF to produce fluorine and hydrogen. Hydrogen, the byproduct of the operation, was vented to the atmosphere. The purified fluorine was stored in tanks in the X-342B Fluorine Storage Building, where it could be transferred into gas cylinders on the covered porch or piped to areas within the plant via the fluorine distribution system (as needed). The electrolyte used to produce fluorine is lithium fluoride (LiF), and potassium fluoride (KF) is used for purification. Sodium fluoride is contained in traps. The HF for fluorine generation is stored in eight steel cylinders, each capable of holding 850 lb (DOE 1993; TPMC 2006c).

The X-344A UF_6 Sampling Facility was originally constructed in 1958 to convert UF_4 to UF_6 and housed 40 fluorine generators and a flame tower. The building was abandoned in 1962 after the operation was discontinued. In the mid-1970s, the building was converted to a high assay sampling area, but this function was terminated in 1975. Equipment supporting the high assay sampling was removed to accommodate an increased market for LEU to fuel nuclear power reactors. In this capacity, the facility was used to transfer up to 5 percent assay of UF_6 from on-PORTS-use-only cylinders into customer-owned cylinders for shipment. Sampling was also conducted. Other parts of this building are used to stage, store, and weigh UF_6 cylinders. A large cylinder yard is located to the south and west of the building. The second floor of the building is used to store used, empty 12-in. UF_6 cylinders and heating, ventilation, and air conditioning equipment (DOE 1993; TPMC 2006c).

By comparing the potential for residual contamination in the buildings to contaminants that have historically released in this quadrant, the following COPCs from these buildings were identified:

- Uranium (uranium-234, uranium-235, and uranium-238)
- Total uranium
- Technetium-99
- Plutonium-239
- Neptunium-237
- VOCs (e.g., TCE)
- SVOCs (e.g., PAHs)
- PCBs
- ACMs
- Potassium fluoride
- Lithium fluoride
- HF
- Arsenic
- Barium
- Beryllium
- Cadmium
- Chromates (including Cr-III and Cr-VI)
- Lead

- Mercury
- Silver.

5.1.2 Exposure Assessment

Exposure of potential receptors to COPCs in each quadrant depends on the physical setting of the area, how contaminants migrate from the sources, and the resultant contaminated media. The buildings and COPCs listed above are the main sources for the current and future contamination within each quadrant at PORTS. Exposures could be expected from other buildings, but these are the major contributors to potential future threats to human health and the environment. As noted above, documented releases from these buildings and others in the past have contributed to the contaminated environmental media. Because these constituents remain in the buildings, future releases as these buildings degrade could increase contaminant mass in media outside the buildings.

To gain a better understanding of how contamination can move through PORTS, a brief description of the groundwater and soil characteristics is provided. As discussed in Section 3.6, groundwater flow at PORTS can generally be divided into four separate flow quadrants. The direction of groundwater flow in Quadrant I, the southern portion of the facility, is controlled by the presence of surface drainages (Big Run Creek and the Southwest Drainage Ditch), the storm sewer system, and bedrock topography. Based on the soils located in this quadrant, contaminants are expected to migrate slowly because of the clay characteristics. Groundwater flow in Quadrant II, in the eastern flow region, is bounded by Little Beaver Creek, which serves as the local surface water discharge point for shallow groundwater. Because of the thick shale and abundance of clay minerals, the retardation of contaminants is great and contaminant movement is expected to be very slow. Groundwater flow in Quadrant III, the western flow region, is primarily influenced by the X-2230N Holding Pond and the West Drainage Ditch. Contaminant migration through the soil is expected to be similar to that in Quadrant I. Groundwater flow in Quadrant IV, in the northern portion of the facility, is strongly controlled by Little Beaver Creek, the North Drainage Ditch, and to a lesser extent, the Northeast Drainage Ditch. Based on the thick shale and clay minerals, contaminant movement through the soil to groundwater is greatly retarded.

As the buildings degrade, contaminants will be released initially by surface rinse/runoff for any removable contamination. As the buildings and equipment further degrade over time and the PGE breaches, further releases of contamination will occur. The surrounding soil and sediments would be the first media to become contaminated. Surface water runoff and air dispersion and deposition would increase the spread of contamination. Mobile contaminants would move through soil via infiltration and move to surface water bodies and groundwater. Nonmobile constituents would tend to stay on PORTS and slowly migrate via surface run-off. These conclusions are supported by previous RCRA investigations (DOE 1996a, 1996b, 1996c, and 1996d) showing that chlorinated hydrocarbons and metals migrate to groundwater, which can be a threat to a hypothetical future on-PORTS resident. Likewise, there is evidence that low concentrations of PCBs are in soils (Quadrant I, II, III) and migrating to surface water bodies (Quadrant I).

The following paragraphs present general information on the mobility and chemical characteristics of the COPCs identified in the previous section that are most likely to still be present in the buildings and how they behave in various environments. This information supports a determination of which media are likely to be influenced by future releases of these contaminants.

Asbestos – Asbestos is the name given to a group of fibrous, naturally occurring silicate minerals. They are resistant to heat and most chemicals; therefore, they are used in insulation materials. The fibers do not evaporate into air or dissolve in water and are for all practical purposes inert. They do not tend to migrate through soil (Barbalace 2004). However, they can become airborne as particulate matter, referred to as friable asbestos. They can contaminate the surface soil around a building in which they have been used as construction materials.

PCBs – PCBs are a class of chemicals in which two to 10 chlorine atoms are attached to a biphenyl molecule. The PCB compounds are categorized by their degree of chlorination. PCB compounds in the United States were produced under the trade name Aroclor. The two prevalent cogeners of the Aroclors at PORTS (and those sampled in the previous RCRA investigations) are Aroclor-1254 and Aroclor-1260. The water solubility and organic carbon partition coefficient of each is listed below. Aroclor-1254 has more than an order of magnitude greater solubility than Aroclor-1260, but both have fairly low solubilities. The organic carbon partition coefficient or K_{oc} indicates the tendency of a chemical to adhere to organic carbon. The higher the K_{oc} value, the more likely the chemical adheres to organic material in soil, sediment, or suspended particles in water. PCBs are very persistent because they do not readily break down in the environment. In water, a small amount of PCBs may remain dissolved and thus can migrate, although most are adsorbed onto organic particles and bottom sediments. Table 5.5 presents the solubility and organic carbon partition coefficient data for the two PCB cogeners.

Table 5.5. Chemical Parameters for PCBs

PCB	Water Solubility (mg/L)	Organic Carbon Partition Coefficient (mL/g)
Aroclor-1254	0.0034	75,600
Aroclor-1260	0.000284	207,000

Source: ORNL 2011

ORNL = Oak Ridge National Laboratory
PCB = polychlorinated biphenyl

Chromium – Chromium occurs in nature, mostly as chrome iron ore or chromite. Although widely distributed in soils and plants, it is rare in natural waters. In most soils under reducing conditions, chromium will be present predominantly in the chromium III state, which has low solubility and very low mobility, thus, chromium does not move significant distances in soil. A field trial on the application of wastewater treatment sludge to soils found movement of heavy metals, including chromium, from the soil surface to a depth of 10 cm, but most of the metal remained in the upper 5 cm of soil. Thus, chromium is not likely to migrate from soil to groundwater. However, chromium VI species may be present, particularly under highly oxidizing conditions. Due to the higher solubility of chromium VI, its mobility in groundwater is higher. Chromium has been detected in groundwater at PORTS. Chromium compounds are very persistent in surface water. Most of the chromium in surface waters may be present in particulate form as sediment. The exact chemical forms of chromium in either medium are not well defined as typically species analysis is not conducted at PORTS. The solubilities of several chromium compounds are listed in Table 5.6. To account for the uncertainties in chromium oxidation states in the environment in the absence of specific sample data, the streamlined risk assessment assumes that both more toxic chromium VI, as well as the less toxic chromium III species, are represented by the total chromium sample results. This provides a conservative assessment of risks associated with exposures to chromium and assures that, if warranted, remedial actions specific to chromium may be considered.

Table 5.6. Solubility of Chromium Compounds

Chemical Form	Oxidation State	Solubility	Units
Chromium chloride	+2	Soluble in cold water	NA
Chromate (lead salt)	+6	0.2	mg/L
Chromate (sodium salt)	+6	873	g/L at 30°C
Dichromate (sodium salt)	+6	2,380	g/Lat 0°C
Chromium dioxide	+4	insoluble	NA
Chromium sulfate	+2/3	insoluble	NA
Chromium trioxide	+3	617	g/L at 0°C

Source: EPA 2011c

EPA = U.S. Environmental Protection Agency
NA = not applicable

Technetium – Technetium exists in valence states from +7 to -1. The most stable states in the environment are +7 and +4. In the +7 state (oxidizing conditions), dissolved technetium exists as the pertechnetate anion, which is highly soluble and mobile in most oxidizing systems. In the +4 state, technetium exists as the tetravalent cation and is relatively immobile (EPA 2004). Several studies have evaluated soil partition coefficient or K_d values. Site-specific K_d values have been measured for various geologic materials at PORTS. The technetium-99 K_d value measured in the Minford Formation ranged from 2.72 mL/g to 4.97 mL/g, indicating moderate potential for migration. Technetium-99 degradation occurs as a result of radiological decay. However, the radiological half-life is extremely long; thus, appreciable degradation will not occur.

Uranium – Uranium can exist in the +3, +4, +5, and +6 oxidation states. The +4 and +6 states are the most common in the environment. These oxides are not very soluble, but will gradually form hydrated uranium oxides in moist conditions. They will slowly dissolve and be transported into the surrounding soil, pore water, and groundwater. The +6 form (uranyl ion) can be adsorbed to clays and organic compounds. The U+4 state solid phases have relatively low solubilities, and their concentrations in water are relatively low (3 to 30 mg/L). The +4 state typically adsorbs strongly to mineral surfaces and partitions into organic matter. These properties lead to its reduced mobility in water (EPA 2006). The form of uranium inside the PGE at removal is uranyl fluoride (UO_2F_2) with minor residual UF_6 which upon contact with moisture will form HF and UO_2F_2. Although this form of uranium is soluble, it does not migrate. Placement of equipment with residual UO_2F_2 in scrap yards or landfills has not shown uranium migration to water sources, thus indicating an insoluble form of uranium being formed shortly after leaving the fluoride compound in the environment (perhaps due to the clay minerals in soil). The measured K_d in the Minford soil formation ranges from 3.67 mL/g to 118 mL/g, indicating little potential for mobility. Further evidence of the lack of mobility of uranium is shown via the historical soil data (see Tables 5.1 through 5.4) where detections of total uranium are found in the surface soils (0 to 2 ft), lesser in subsurface soils (0 to 10 ft), and very rarely in water samples. There are some detections of total uranium in sediment samples, which most likely are from washout and overland movement. Uranium degradation occurs as a result of radiological decay, generating a variety of radium isotopes. However, the radiological half-lives (time required for half of the concentration to be lost due to degradation) of the uranium isotopes are extremely long; thus, appreciable degradation will not occur.

TCE – TCE is a nonflammable, colorless liquid at room temperature and has a somewhat sweet odor. It is mainly used as a solvent to remove grease from metal parts. Volatilization is the primary means of eliminating TCE from soil. Henry's Law constant (0.403) and vapor pressure (69 mm Hg) indicate a propensity to volatilize or partition to the air phase. TCE is readily mobile in soil and is primarily affected by the organic carbon content (Log K_{oc} values range from 2.03 to 2.66 mL/g) (Garbarini and Lion 1986). TCE that has not volatized tends to migrate to groundwater (solubility at 20°C is 1.070 g/L) (Agency for Toxic Substances and Disease Registry [ATSDR] 1997a). While TCE in surface water readily evaporates, it can remain in groundwater for long periods of time. Degradation of TCE in groundwater occurs with a half-life of approximately 10 years.

A discussion of the potential exposure routes and the receptors that could be exposed to contaminants in media as a result of the transport mechanisms discussed above follows.

Under the no-action alternative, building S&M is assumed to cease, building waste would not be disposed of properly, and contaminants found in the buildings, including those in PGE, would be released to the environment. Therefore, there is the potential that receptors could come onto PORTS and be directly exposed to the contaminants in the buildings or waste after degradation. The CSM (Figure 5.2) shows the relationship between the sources of contamination and the potential receptors, including on-PORTS receptors (residents/trespassers and industrial workers) and off-PORTS receptors (plant neighbors and other members of the public near the plant).

The exposure assessment identifies and provides a discussion of the potential receptors that could be exposed to contaminants in the buildings or in media as a result of transport from the contaminant sources previously described to the locations where receptors come into contact with those contaminants. The receptors considered in this streamlined evaluation of threats to human health include both on-PORTS (within the boundary of PORTS) and off-PORTS (outside the boundary of PORTS) receptors in the most likely down-gradient locations from the sources. Potential receptors are identified along with the exposure pathways associated with the various exposure media. The following sections present the exposure assessment by receptors, both on PORTS and off PORTS.

On-PORTS receptors

Three types of receptors are to be considered for the on-PORTS scenario: a trespasser, an on-PORTS industrial worker, and an on-PORTS resident. Under the no-action alternative, there is a potential for receptors to trespass into the decaying or fallen buildings. There is a potential for other on-PORTS receptors, including on-PORTS industrial workers and future on-PORTS residents at PORTS, to be exposed to contaminants from the process buildings, complex facilities, and other support facilities. Such exposures could occur by inappropriate future use of the buildings and equipment/materials in the buildings or if migration of contaminants from the buildings occurs. In the case of on-PORTS users of the buildings or waste piles, direct contact with contamination is likely. Although most of the contamination is contained in secondary structures (PGE), it could be released through metal oxidation (corrosion) and ultimately wash out through breaches in the metal or through active physical disturbance. While corrosion rates vary widely based on metallic make-up and environmental conditions, corrosion of the equipment shells will occur and may accelerate once removed from the protection of the building structure. In addition to being directly exposed to contaminants in the building surfaces or associated waste, contaminants released from the buildings could migrate into immediately surrounding environmental media. The migration pathways include the migration of contaminants in air (as dust particulates and/or volatilization), in surface water as runoff, and in groundwater.

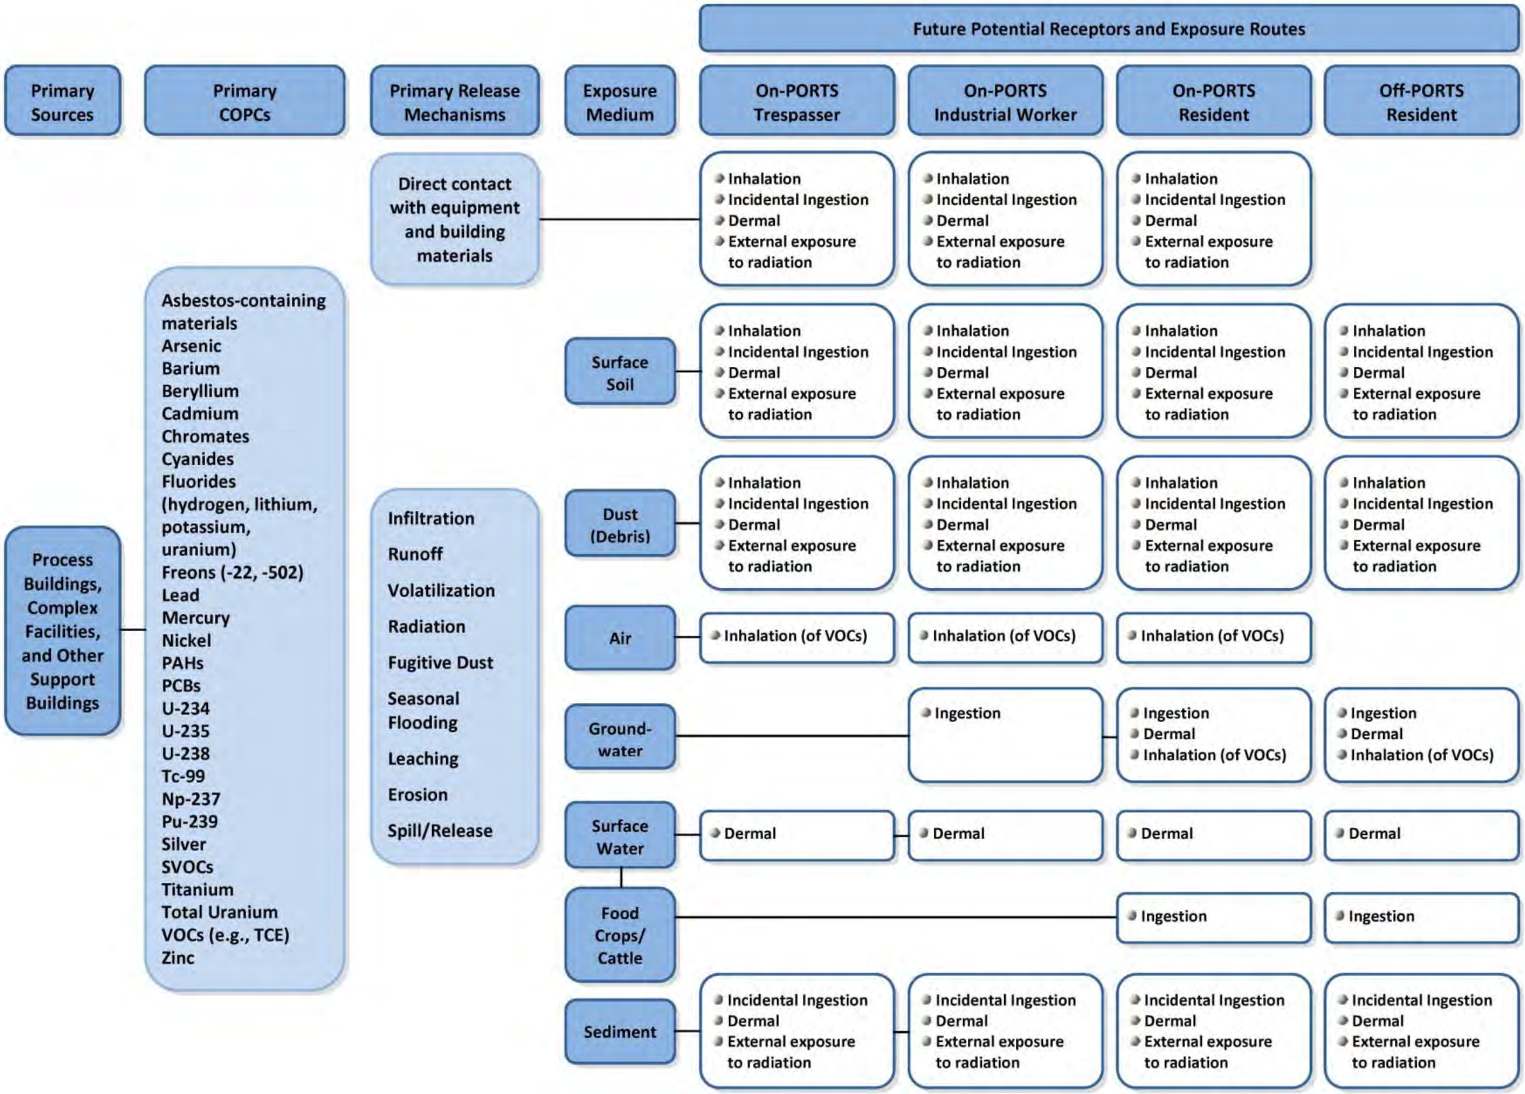

Figure 5.2. PORTS CSM for Human Receptors

- Trespassers – The trespasser is assumed to periodically traverse the industrialized area of the plant, perhaps exploring or recreating in or immediately adjacent to the buildings. They would have intermittent exposure to building materials and to the contents within the buildings, including potentially stored solvents. They would also have exposure to soil adjacent to the buildings, which may have become contaminated. The exposure routes of concern for the trespasser include:
    - Inhalation of particulates from contaminated equipment and building materials, dust from waste, surface soil, and VOCs in air (near dip vats)
    - Incidental ingestion of particulates from contaminated equipment and building materials, dust from waste, surface soil, and sediment
    - Dermal contact from contaminated equipment and building materials, dust from waste, surface soil, sediment, and surface water
    - External exposure from ionizing radiation from contaminated equipment and building materials, dust from waste, surface soil, and sediment.
- On-PORTS Industrial Worker – This receptor is a worker whose activities are in or near the deteriorating structures. The individual uses the building or building waste inappropriately in the future under a loss of institutional controls. The worker could be working inside or outside. The worker would consume groundwater from the plant. It is also assumed that the workers would not consume surface water from PORTS but that they could have contact with nearby surface water bodies. The exposure routes of concern for the on-PORTS industrial worker include:
    - Inhalation of particulates from contaminated equipment and building materials, dust from waste, surface soil, and VOCs in air (near dip vats)
    - Incidental ingestion of particulates from contaminated equipment and building materials, dust from waste, surface soil, and sediment
    - Dermal contact from contaminated equipment and building materials, dust from waste, surface soil, surface water, and sediment
    - External exposure from ionizing radiation from contaminated equipment and building materials, dust from waste, surface soil, and sediment
    - Ingestion of groundwater.
- On-PORTS Resident – The on-PORTS resident is an upper bound receptor and assumes that humans set up residence adjacent to or among the deteriorating structures. It is an unlikely receptor but is included in this analysis as a reference point for decision makers. This receptor is assumed to engage in subsistence farming and uses groundwater from the plant. Surface water is assumed to be used as an irrigation source for crops instead of groundwater as the groundwater yields on the plant are typically low. The median yield for the Gallia is reported to be 0.6 gpm, which is equivalent to only 864 gal/day. While this yield may be sufficient for small household use, numerous wells would be required to support crop irrigation. For example, the minimum yield to irrigate 1 acre is 5 to 10 gpm, operated approximately 20 hours/day (6,000 to 12,000 gal/day for 1 acre) during the summer. The exposure routes of concern for the on-PORTS resident include:

  - Inhalation of particulates from contaminated equipment and building materials, dust from waste, surface soil, VOCs in air (near dip vats), and groundwater
  - Incidental ingestion of particulates from contaminated equipment and building materials, dust from waste, surface soil, and sediment
  - Dermal contact from contaminated equipment and building materials, dust from waste, surface soil, surface water, sediment, and groundwater
  - External exposure from ionizing radiation from contaminated equipment and building materials, dust from waste, surface soil, and sediment
  - Ingestion of groundwater and food crops and livestock (cattle) irrigated by surface water.

Off-PORTS receptors

The off-PORTS receptor considered is a resident. This is the most conservative receptor because exposure parameters are highest compared to other receptors. Currently, contaminated air, soil/sediment, and surface water on PORTS have not reached any off-PORTS media to which an off-PORTS residential receptor may have come in contact (DOE 2010b; DOE 2010c). In 2004, TCE was detected in groundwater from an off-PORTS monitoring well south of the DOE property; however, TCE levels were less than the drinking water standard of 5 µg/L. Mitigation measures have been put in place, and current monitoring data indicate that the off-PORTS contamination has been reduced to less than 1 µg/L of TCE (DOE 2011b).

- Off-PORTS Residents – These are plant neighbors who live along the DOE boundary and could be potentially exposed on a long-term basis to contaminants released from buildings and migrating off PORTS.

  Under the no-action alternative, there is a potential for off-PORTS residents near the PORTS boundary to be exposed to contaminants migrating from the deteriorated process buildings, complex facilities, and other support facilities. Contamination off PORTS could result from the migration of contaminants in air (as wind-generated particulates with exposures dependent on wind direction, as indicated in Figure 3.3), in surface water as runoff, and in groundwater. The potential exposure routes of concern from these migration pathways would include the following:

  - Inhalation of particulates from wind-blown dust from waste and surface soil and of VOCs in groundwater
  - Incidental ingestion of particulates from wind-blown dust from waste and surface soil as well as sediment
  - Dermal contact from wind-blown dust from waste and surface soil as well as surface water, sediment, and groundwater
  - External exposure from ionizing radiation from wind-blown dust from waste and surface soil as well as sediment
  - Ingestion of groundwater and food crops and livestock (cattle) irrigated with surface water.

Potential residential exposure to surface water, as shown in the CSM (Figure 5.2), would also be a secondary exposure pathway because surface water could be used for irrigation of crops and as a drinking source for cattle. However, this pathway is considered to be insignificant in terms of exposure relative to the other primary exposure pathways. Groundwater was not considered as a source for irrigation or a drinking source for cattle because there is not enough volume to serve as an adequate supply.

5.1.3 Toxicity Assessment

Table 5.7 presents the carcinogenic class, primary human health exposure pathways, and primary target organs for potential systemic and/or cancerous effects from the expected COPCs. A brief summary of effects and toxicity is also provided.

Table 5.7. Health Data for Expected COPCs

Chemical of Primary Concern	Carcinogen Class[a]	Human Health Exposure: Primary Pathway(s) of Concern	Primary Target Organ(s) (for Systemic and/or Cancer Effects)	Reference for Carcinogen Class and Target Organs
Arsenic	A	Ingestion, inhalation	Liver, skin, gastrointestinal tract, bladder, lungs, kidney, nasal passages, liver, respiratory tract, prostate	EPA 2012 (IRIS)
Asbestos (friable)	A	Inhalation	Lung, asbestosis, mesothelioma	EPA 2012 (IRIS)
Barium	D	Ingestion	Gastrointestinal	EPA 2012 (IRIS)
Beryllium (and compounds)	B1	Inhalation, ingestion	Lung, bone, liver, kidneys, nasal ulcers, small intestine, spleen, berylliosis	EPA 2012 (IRIS)
Cadmium	B1	Inhalation, ingestion	Lung, kidney, prostate, bladder, stomach, bones, (toxic)	EPA 2012 (IRIS)
Chromium VI	A	Ingestion, inhalation, dermal	Lung, developmental effects, skin, gastrointestinal, stomach ulcers, male reproductive system	EPA 2012 (IRIS)
Cyanide	D	Inhalation, oral, dermal	Lung, central nervous system, convulsions	ATSDR 2006
Fluorides (Hydrogen)	D	Inhalation, ingestion, dermal	Lung, gastrointestinal, heart, skeletal, liver, and kidney	ATSDR 2003
Freons	D	Inhalation, dermal	Lung, skin	Brown 1988
Lead	B2	Ingestion, inhalation	Central nervous system, bone, kidney, neuropsychological impairment	EPA 1989; EPA 2012 (IRIS)
Mercury (elemental)	D	Inhalation of vapors	Central nervous system, kidney, developmental effects, gastrointestinal, eyes, urinary system	EPA 2012 (IRIS)
Nickel (insoluble compounds)	A	Inhalation, ingestion	Lungs, nasal, respiratory tract, kidney, immune system effects	ATSDR 2005
PAHs	B1-B2	Inhalation, ingestion, dermal	Lung, stomach, skin	ATSDR 1995

Table 5.7. Health Data for Expected COPCs (Continued)

Chemical of Primary Concern	Carcinogen Class[a]	Human Health Exposure: Primary Pathway(s) of Concern	Primary Target Organ(s) (for Systemic and/or Cancer Effects)	Reference for Carcinogen Class and Target Organs
PCBs	B2	Ingestion, inhalation, dermal	Liver, hepatocellular tumors	ATSDR 2000
TCE	C-B2	Inhalation, ingestion, dermal	Liver, kidney, skin, reproductive system, blood, central nervous system, lungs	EPA 2012 (IRIS)
Silver	D	Inhalation, dermal	Lungs and skin	EPA 2012 (IRIS)
Titanium (titanium tetrachloride)	D	Inhalation, dermal	Lung, skin	ATSDR 1997b
Zinc	D	Inhalation, ingestion	Lung	EPA 2012 (IRIS)
Uranium-total (soluble compounds)	D	Inhalation, ingestion	Lungs and kidney	ATSDR 2011
Uranium-234	A	Ingestion, inhalation, external exposure to radiation	Kidney, lung, tumors, brain, liver, reproductive effects	ATSDR 2011
Uranium-235	A	Ingestion, inhalation, external exposure to radiation	Kidney, lung, tumors, brain, liver, reproductive effects	ATSDR 2011
Uranium-238	A	Ingestion, inhalation, external exposure to radiation	Kidney, lung, tumors (kidney, brain, liver), reproductive	ATSDR 2011
Neptunium-237	A	Inhalation, ingestion, external exposure to ionizing radiation	Lungs, bones/skeleton surface, liver, developmental effects	IARC 2001
Plutonium-239	A	Inhalation, ingestion, external exposure to ionizing radiation	Lungs, respiratory tract, liver, bones/skeleton surface, developmental effects	IARC 2001; ATSDR 2010
Technetium-99	A	Ingestion, inhalation, external exposure to radiation	Thyroid, gastrointestinal	EPA 2002; EPA 2010

[a] Class A = human carcinogen, Class B1 = probable human carcinogen with limited human data, Class B2 = probable human carcinogen with sufficient evidence in animals, Class C = possible human carcinogen, and Class D = not classified (EPA 1989).

ATSDR = Agency for Toxic Substances and Disease Registry
EPA = U.S. Environmental Protection Agency
IARC = International Agency for Research on Cancer
IRIS = Integrated Risk Information System
PAH = polycyclic aromatic hydrocarbon
PCB = polychlorinated biphenyl
TCE = trichloroethene

Asbestos is a Class A carcinogen, which means it is known to cause cancer (asbestosis) in humans, based on epidemiological studies. If appropriate controls are not in place, asbestos has the potential to affect human health and the environment. Chrysolite, the most commonly found form of asbestos, is present in the transite siding at a volume of 12 to 50 percent. This asbestos would continue to become more brittle and friable if not removed. Other forms of asbestos exist in insulation on piping and may become friable as the buildings degrade. Uncontrolled releases of asbestos present a risk to human health and the environment. The exposure pathway for asbestos would most likely be through the air, and the primary pathway of concern would be inhalation with the primary target organ being the lungs.

Arsenic is a Class A carcinogen, which means it is known to cause cancer in humans, based on epidemiological studies. Arsenic is primarily found in process buildings instrument lines and sampling lines as a result of treatment gases and may also be found associated with the chemical trapping systems. Once degradation of these systems occurs, releases and exposures to receptors are likely to occur. There are no large quantities of arsenic in these systems, so the exposures would be in low concentrations. The most likely route of exposure is ingestion of contaminated soils.

Barium is a Class D compound, which means it is not currently classified as causing cancer in humans. Barium was used in the chemical trapping systems within the process buildings. Exposure to barium is likely to be low, based on the quantities used. Ingestion is the primary pathway from contaminated soils and drinking water, leading to gastrointestinal disturbances and muscle weakness at low doses and to kidney toxicity at higher doses.

Beryllium is a Class B1 carcinogen, meaning it is a probable human carcinogen. The primary exposure route is inhalation. Acute and chronic berylliosis of the lungs can occur upon inhalation of beryllium and its compounds. Beryllium can be found, for example, in the machine shop and compressor shop areas of the process buildings in low parts per million quantities. If released to the environment, the potential for human exposure via inhalation is increased.

Cadmium is a Class B1 carcinogen; it is cancer probable human carcinogen, based on epidemiological studies. Small amounts of cadmium can be found in association with the chemical trapping materials in the process buildings. When degradation or disturbance of these traps occurs, releases of cadmium are likely. The main exposure routes to receptors are via ingestion and inhalation of contaminated soils. The quantities of cadmium are expected to be small, and exposures would be negligible.

Chromium VI is a Class A carcinogen by the inhalation route of exposure. Chromium compounds were used to prevent corrosion in the RCW treatment system until 1990 when treatment of cooling water was changed to a phosphate-based system. Residual chromates reside in the RCW systems in several structures. As this system degrades, releases of chromium VI are likely. Ingestion, inhalation, and dermal exposures are the main routes to receptors via releases to soils.

Cyanide is a Class D carcinogen, which means it is not currently classified as causing cancer in humans. The predominant uses of cyanides are in the steel electroplating and mining industry, with the main route of exposure through inhalation in this setting. However, ingestion via soil and groundwater may also occur. Low dose exposures may cause cardiovascular disturbances, while higher dose exposures cause central nervous system toxicity.

Fluorides (Hydrogen) are Class D carcinogens, which means they are not currently classified as causing cancer in humans. They typically are in the form of gases and are irritating to the eyes, nose, and skin. Breathing large amounts of HF can harm the lungs and heart. These compounds are most likely found in the process piping and the Feed, Transfer, and Sampling Facilities. Releases are expected to be periodic as breaches in systems occur. The routes of exposure include inhalation, ingestion, and dermal exposure.

Freons are Class D carcinogens, which means they are not currently classified as causing cancer in humans. Inhalation and dermal routes are the primary modes of exposure. Frostbite may occur due to liquid exposure to the skin, and inhalation of Freon vapors may cause central nervous system impacts, while prolonged exposure may lead to heart irregularities.

Lead is a Class B2 carcinogen, which means it is a probable human carcinogen. Lead-based paint is expected to be present in many of the painted structures because of the age of the buildings. Other forms of lead expected to be present would be in the form of solder from tubing fittings. The lead paint would pose a threat to human health if it were to become airborne (such as through mobile dust) or if it were subjected to heat. The primary routes of exposure would be ingestion and inhalation with the primary target organs being the central nervous system, bones, and kidneys. Neuropsychological impairment would be a systemic effect from exposure; children are particularly susceptible to exposure to lead.

Mercury is a Class D carcinogen, which means it is not currently classified as causing cancer in humans. The primary exposure route of concern is inhalation of mercury vapors. The crucial target organ is the brain. Mercury primarily has adverse effects on the central nervous system and can cause developmental effects in children. Mercury is expected to be present in such places as temperature/pressure contact switches, chemical traps, fire pull stations, and mercury vapor lamps. If released to the environment, the potential for human exposure via inhalation is increased.

Nickel (insoluble compounds of) is a Class A carcinogen, which means it is known to cause cancer in humans. The insoluble forms primarily impact the inhalation and ingestion pathways. The lungs, respiratory tract, kidneys, and immune system are the primary target organs/systems. Nickel in the form of nickel plating is located within the PGE and would be released from breaches of the equipment. The plating would need to go through oxidation before becoming available to receptors.

PAHs are a group of over 100 different chemicals, many of which are Class B1 and B2 carcinogens, meaning there is evidence of being a probable carcinogen in humans (B1-limited human data; B2-sufficient animal data). PAHs particularly affect the lungs via inhalation, stomach via ingestion, and skin via dermal exposure. These chemicals are primarily associated with discharges from industrial and wastewater treatment plants.

PCBs are Class B2 carcinogens, which means they are a probable human carcinogen. PCBs are particularly harmful to the liver via the ingestion exposure route. PCBs may be found in fluorescent lights with PCB ballasts, ventilation systems, and oils containing PCBs, although manufacture of PCBs was stopped in the United States in 1977. Also, PCBs can be found in older paints.

Silver is a Class D carcinogen, which means it is not currently classified as causing cancer in humans. The primary exposure route is via inhalation and dermal exposure. Chronic inhalation of silver oxide and silver nitrate dusts may result in chronic respiratory irritation, while dermal exposures may cause argyria, a permanent gray discoloration of the skin. Uses of silver included small amounts in the form of silver solder for tubing fittings and other applications.

TCE is a Class C-B2 carcinogen, meaning it is a possible/probable human carcinogen. TCE can be harmful to, for example, the liver, kidneys, lungs, and central nervous system. The primary exposure routes are inhalation and ingestion.

Titanium is a Class D carcinogen, which means it is not currently classified as causing cancer in humans. As titanium tetrachloride, it is irritating to the skin, lungs, and mucous membranes. Inhalation of large doses can damage the lungs. It strongly reacts with water to form hydrochloric acid. Titanium dioxide may cause gastrointestinal irritation via ingestion.

Zinc is a Class D carcinogen, which means it is not currently classified as causing cancer in humans. Its toxicity is considered to be relatively low, and ingestion of excessive levels may lead to nausea, epigastric distress, and anemia. Inhalation of high concentrations can cause metal fume fever.

Total uranium (including soluble compounds of uranium in which the predominant adverse health effect is systemic toxicity) is classified by EPA to be a Class D carcinogen, which means it is not currently classified as causing cancer in humans. The primary modes of exposure to uranium are ingestion and inhalation (dermal exposure is typically only applicable to water soluble forms of uranium). According to EPA, the primary toxic effect is damage to the kidneys. Additionally, workers in industry who have inhaled UF_6, a component introduced into the process gas system at PORTS, experienced respiratory tract irritation. However, this response was thought to be associated with the hydrofluoric acid, a component present when UF_6 is heated to a gaseous form, rather than from the uranium.

Radionuclides are Class A carcinogens, which means they are known to cause cancer in humans via a variety of exposure routes, depending on the specific radionuclide in question. Exposure to high levels of uranium isotopes (uranium-234, uranium-235, and uranium-238 in particular) can cause kidney, liver, and lung cancers/tumors from direct exposure, inhalation, and ingestion. Technetium-99 can cause thyroid and gastrointestinal cancers, primarily from the ingestion and inhalation exposure pathways. There are measureable amounts of neptunium-237 and plutonium-239 within the process buildings as a result of contaminants present in feed materials generated from reactor returns. Both neptunium-237 and plutonium-239 can cause lung, bone, and liver cancer, and developmental effects in children through direct exposure, inhalation, and ingestion. If released to the environment, the potential for human exposure to radionuclides via inhalation, ingestion, and direct exposure is increased.

5.1.4 Risk Characterization

The risk characterization estimates the potential for adverse health effects as a result of exposure to contaminants and the associated toxicity characteristics of the hazardous substances. In a quantitative assessment, this process culminates with a list of COCs as well as pathways of concern. COCs are those contaminants that are in sufficient concentrations in media to pose a threat to humans. This information guides alternative development to ensure that any action taken addresses the risk posed by exposure to PORTS contaminants. For a qualitative risk assessment, COCs are identified from the list of COPCs, using the understanding of the prevalence of the contaminants in remaining sources, their potential for release and/or migration, and their inherent toxicity.

The pathways of concern are identified as a result of the typical contribution of the pathways when risk is quantified. For instance, the use of surface water to irrigate crops generally is inconsequential compared to ingestion of groundwater.

If the PORTS buildings and structures are allowed to remain in place without maintenance over time, the wind, rain, and freeze/thaw cycles would cause degradation of building structures, eventually resulting in failure of the structures (e.g., roof leaks/failures, asbestos transite siding blowing off buildings and structures, and concrete crumbling and collapsing). In turn, this may result in an increased threat of exposure to receptors. Additionally, oxidation of metal components may eventually lead to decay, resulting in breaches that allow infiltrating water to wash out contaminants, allowing them to move away from the components in an overland flow to surface water. Threats to human health from exposure to contaminants such as asbestos, PCBs, lead, mercury, beryllium, uranium (metal/soluble compound), TCE, technetium-99, or uranium isotopes are minimal under current conditions. However, future uncontrolled releases would cause increased threats to human health via the exposure pathways discussed above. As these buildings continue to age, the threat of radiological and chemical substance releases would increase and actual releases to the environment would increase. Radiological and chemical substances could be released directly to the environment through, for example, a breach in a containment wall, roof, or other physical control as the buildings age and deteriorate. In addition to degradation causing a release, there is the potential that future users of the plant may breach the PGE and buildings, becoming exposed to what are safely encased contaminants and causing a sudden release of these contaminants.

The following sections discuss COCs and most likely receptors that would be impacted by those COCs by quadrant and environmental media. The COC identifications are based on quantities anticipated to be present (as a result of process knowledge), associated toxicity, and the mobility of these contaminants in the environment.

Quadrant I

The most likely receptors exposed to the ACM include the future trespasser, on-PORTS worker, and on-PORTS resident. The inhalation pathway would be the primary mode of exposure. Because of its physical nature (does not migrate far) and the distance to the plant boundary, the off-PORTS resident is not likely to be exposed to ACM.

PCBs are ubiquitous in buildings and would migrate to soils. PCBs are not very mobile. As a result of previous releases, PCBs have been detected in surface water in this quadrant. There is a potential for accumulation in sediments, which may cause unacceptable risks for the on-PORTS resident through ingestions and dermal contact. Given no action, PCBs could migrate off PORTS in the future through surface water pathways.

In the buildings, TCE is expected to still be present in large enough quantities to be considered a source for the trespasser, on-PORTS worker, and on-PORTS resident via inhalation. Cleaning operations took place within X-710, which is considered a source of the existing plume. Based on the mobility of TCE and the presence of an existing plume, releases of TCE from this quadrant could continue to be a future impact to groundwater and a threat to industrial workers and on-PORTS residents through ingestion. The expected TCE concentrations would not be as great as those currently in the environment because operations have been shut down. It is not likely that off-PORTS receptors would be impacted.

Other COPCs were not considered to be in large enough quantities to result in unacceptable risks to receptors and thus are not COCs. Most of the metal COPCs are likely in small quantities in solder and switches. Most of the laboratory waste from past operations was already disposed, and only minor contamination is expected. Therefore, the following are COCs associated with Quadrant I:

- ACM
- PCBs
- TCE.

Quadrant II

Based on operations at the buildings in Quadrant II, radioactive contamination and associated risks are expected to be unacceptable to the on-PORTS receptors. The risks to the worker and on-PORTS resident are expected to be greater than those to the trespasser (based on higher exposure frequency and duration). The main routes of exposure would be external exposure to ionizing radiation and incidental ingestion. The uranium isotopes are not very mobile, and soil is the most likely medium for exposure through external radiation. Technetium-99 is very mobile and may migrate to underlying groundwater. Ingestion of on-PORTS groundwater by a future industrial worker or on-PORTS resident could result in an unacceptable risk. Technetium-99 is unlikely to stay in the soil long enough to cause a risk due to its low K_d, suggesting that technetium-99 is moderately mobile in soils.

Based on the operations, ACM is ubiquitous in the building materials and may impact the on-PORTS receptors via inhalation.

Based on operations in Quadrant II buildings, it is likely that TCE would be a source, and exposures to on-PORTS receptors are more likely via inhalation. TCE was used in the X-705 Decontamination Building, X-705A/B, and the X-720 Maintenance Building and neutralization pit. As a result, local TCE spill sites throughout this area of PORTS are likely to have been, and may still be, sources of TCE groundwater contamination (DOE 2001a). The most likely exposed receptors to future TCE releases to groundwater are the on-PORTS industrial worker and resident, and the pathway with the greatest risk potential is groundwater ingestion.

PCBs are prevalent in the buildings throughout this quadrant. If released, PCBs could be a concern in on-PORTS soils through ingestion and dermal contact.

Chromium is expected to be a concern because X-705D served to circulate RCW, which contained chromium compounds, through X-705. Hexavalent chromium would be a risk to on-PORTS receptors via inhalation or ingestion of contaminated soils. It has been associated with groundwater contamination and may be an issue for on-PORTS residents through inhalation or ingestion of groundwater and for the industrial worker through ingestion.

Other COPCs are not expected to be present in large enough quantities to pose a risk or hazard to human receptors. Similar to Quadrant I, metals are not expected to be released in great quantities, and any metals detected in groundwater were from past operations. Therefore, the following are COCs associated with Quadrant II:

- Uranium and uranium isotopes (uranium-234, uranium-235, and uranium-238)
- Technetium-99
- ACM
- TCE
- PCBs
- Chromium.

Quadrant III

This Quadrant contains two of the process buildings and thus contains large quantities of uranium and technetium-99. Based on a limited early sampling event focused on both the converter shells and tubes, technetium-99 concentrations averaged 84,000 pCi/g in X-326. This concentration is above a soil PRG (DOE 2011c) for human health and clearly demonstrates that the converters are a potential future source of this radionuclide. Likewise, uranium concentrations in the process buildings are in the 10,000 pCi/g range and also indicate that there are continuing uranium sources. Once degradation of the PGE occurs, releases of UF_6 (the form of uranium in equipment) will occur, and upon contact with moisture, HF and UO_2F_2 will be formed. Although this form of uranium is soluble, historic releases via the atmosphere and subsequent deposition to soils have not shown migration to water sources, thus indicating an insoluble form of uranium in the environment. Technetium-99 is mobile and likely to migrate to water sources, where it could be a threat through ingestion. The other radionuclides, neptunium-237 and plutonium-239, are in much smaller quantities and are not expected to cause unacceptable risks.

Because of the large sizes of the process buildings, it is expected that large quantities of ACM could become a source of risk for on-PORTS receptors. Inhalation is the most likely exposure pathway.

Large quantities of PCBs from seals and gaskets in ductwork could be a future source of unacceptable exposure to receptors. Soil is the main medium of exposure, as discussed for the other quadrants. If migration to surface water does occur, dermal exposure to contaminated sediment is a potential for the on-PORTS resident and to lesser levels, off-PORTS receptors.

Chromium is expected to be present and associated with the RCW lines, and present an unacceptable risk to on-PORTS receptors through soil and groundwater via inhalation or ingestion.

The other COPCs are not expected to be released in large enough quantities to impact either on-PORTS or off-PORTS receptors. Although there are many items that contain metals, it is assumed that the degradation of these items may occur slowly over time, and the concentrations released would be minimal. Other metals such as nickel are in the form of plating and would not cause impacts to receptors. Therefore, the following are COCs associated with Quadrant III:

- Uranium and uranium isotopes (uranium-234, uranium-235, and uranium-238)
- Technetium-99
- ACM
- PCBs
- Chromium.

Quadrant IV

The X-333 Process Building is one of the main sources in this quadrant. It contains similar types of contaminants to those in the other two process buildings in Quadrant III, and exposure to receptors would be similar. TCE is an additional contaminant that is considered to be a COC for this quadrant, based on operations conducted in the Feed, Transfer, and Sampling Facilities. Off-PORTS groundwater migration of contaminants would be expected to be limited because of slow degradation of the process buildings, coupled with the fact that groundwater flows in a northern direction with discharge into Little Beaver Creek (Figure 5.1). Resultant surface water concentrations would be low due to dilution but off-PORTS migration is a potential. Therefore, the following are COCs associated with Quadrant IV:

- Uranium and uranium isotopes (uranium-234, uranium-235, and uranium-238)
- Technetium-99
- ACM
- TCE
- PCBs
- Chromium.

Summary. The process buildings, complex facilities, and supporting facilities contain numerous radiological and chemical contaminants that are known carcinogens and/or toxicologically hazardous substances. Under the potential future scenarios, it is anticipated that the expected concentrations of COCs in all applicable exposure media for receptors presented in this streamlined evaluation of threats to human health are at levels exceeding typical risk-based standards (DOE 2013a). Table 5.8 shows the potential completed pathways for the COCs discussed above, should the buildings be allowed to deteriorate and no action be taken to remediate the buildings and structures or dispose of the waste. Unacceptable exposures to human receptors from release of these contaminants are likely to occur if no action is taken. As noted in Table 5.8, potential exposures to contaminants present within and on equipment and building materials likely present unacceptable risks to all three on-PORTS receptors. Additionally, potential exposures to contaminants in soil, sediments, and groundwater likely present unacceptable risks to an on-PORTS industrial worker and to an on-PORTS resident, and to a lesser extent, a future off-PORTS receptor. Under the no-action alternative, the resulting threat to human health from these exposures establishes the need for remedial action.

Table 5.8. Summary of D&D Waste COCs and Potential Completed Pathways for PORTS

		On-PORTS Trespasser	**On-PORTS Industrial Worker**	**On-PORTS Resident**
Media	**COC**	**Exposure Route**		
Building Waste	ACM	Inhalation	Inhalation	Inhalation
	PCB	Ingestion/Dermal	Ingestion/Dermal	Ingestion/Dermal
	TCE	Inhalation	Inhalation	Inhalation
	Uranium	Ingestion/Inhalation	Ingestion/Inhalation	Ingestion/Inhalation
	U Isotopes	Ionizing Radiation	Ionizing Radiation	Ionizing Radiation
	Tc-99	Ionizing Radiation	Ionizing Radiation	Ionizing Radiation
	Chromium	Ingestion/Inhalation	Ingestion/Inhalation	Ingestion/Inhalation
Soil/Sediment	PCB	--	Ingestion/Dermal	Ingestion/Dermal
	Uranium	--	Ingestion/Inhalation	Ingestion/Inhalation
	U Isotopes	--	Ionizing Radiation	Ionizing Radiation
	Chromium	--	Ingestion/Inhalation	Ingestion/Inhalation
Groundwater	TCE	--	Ingestion	Ingestion
	Tc-99	--	Ingestion	Ingestion
	Uranium	--	Ingestion	Ingestion
	Chromium	--	Ingestion	Ingestion/Inhalation

-- = No completed pathway

ACM = asbestos-containing material
COC = contaminant of concern
PCB = polychlorinated biphenyl
PORTS = Portsmouth Gaseous Diffusion Plant
TCE = trichloroethene

5.1.5 Evaluation of Uncertainties

The estimation of uncertainty is fundamental to risk assessments. Types of uncertainty are divided into four broad categories: source term/data evaluation, exposure assessment, toxicity assessment, and risk characterization.

5.1.5.1 Uncertainties in source term/data evaluation

For the streamlined evaluation of the potential threats to human health, a list of contaminants identified in earlier environmental investigations at PORTS was obtained (DOE 2013a) and evaluated as well as process and building material of construction knowledge. The earlier investigations illustrate what has been released to the environment historically related to processes occurring in or around the buildings located within the quadrants. Identifying current and future COPCs using a process of considering the operations and historical releases, both documented and anecdotal, introduces uncertainties into the results. Historical releases may be greater than future releases because of recent efforts to bring the buildings into a safe shutdown mode, lessening the types and levels of contamination in the buildings. Or, future releases may be greater under an assumption of the loss of institutional controls because there would be no effort to control releases in the future. This uncertainty may overestimate or underestimate risk conclusions. For example, while PAHs have been detected in environmental media, including soil and sediment in the vicinity of buildings within three of the four quadrants, there is no evidence that significant sources of PAHs remain in the building such that future releases could result in increases in contaminant load in the environmental media. Therefore, not carrying PAHs forward as COCs is unlikely to result in an underestimate of both carcinogenic and non-carcinogenic risk as a result of exposures associated with the receptors considered in the streamlined evaluation of the potential threat to human health.

5.1.5.2 Uncertainties in exposure assessment

For each receptor in the streamlined evaluation of the potential threat to human health, assumptions are made concerning the routes of exposure, the contaminated media a receptor can be exposed to, and the potential for intake by the different routes of exposure. The most significant uncertainty results from use assumptions of the plant. Although the trespasser is a credible scenario under no action, the use of the plant, as is, for industrial or residential use is unlikely. Then, there is considerable uncertainty in the assumptions of which media will result in exposure to contaminants. Groundwater is not likely to have sufficient yield for household use. These assumptions are likely to overestimate the risk.

5.1.5.3 Uncertainties in toxicity assessment

There are numerous uncertainties associated with the toxicity information derived for chemicals and radionuclides, including carcinogen class, associated exposure routes, and primary target organs, that apply to the evaluation of the potential threat to human health. Such uncertainties include those related to scientific study results that identify the potential for human toxicity, those introduced by the process of deriving carcinogenicity potential, those related to impacts of other factors such as the potential for synergistic or antagonistic interactions, and those related to the assumption of predicting lifetime cancer induction or noncancer health impacts on the basis of less than lifetime exposure. Considering these uncertainties, the EPA has working groups that review all relevant human and animal studies, which themselves have undergone prior peer review, and select the studies most pertinent to the derivation of the specific noncarcinogenic and carcinogenic health impacts. These studies for chemicals often involve data from experimental animal studies using high exposure levels, and exposure under acute conditions (short time periods). Extrapolation of these data to humans, applicable to a lifetime exposure under low-dose chronic conditions, introduces large uncertainty. The magnitude of this uncertainty is addressed by applying uncertainty factors to the dose response data associated with chemical exposure, which provides an adequate margin of safety for use in risk assessments.

Unlike the uncertainty that can exist with toxicity values for chemicals, the uncertainty associated with radionuclide toxicity values is better defined. The dose-response relationship between cancer and ionizing radiation has been evaluated over many years and is well documented from both animal and accidental human exposure. In addition, toxicity values for radionuclides are extrapolated from the cancer induction data established using the Japanese Atomic Bomb Survivors Database and a relative risk projection model basing these values on human data rather than extrapolated from an animal model.

5.1.5.4 Uncertainties in risk characterization

The risk characterization estimates the potential for adverse health effects as a result of exposure to contaminants and the associated toxicity characteristics of the hazardous substances, taking into account the plant conditions, the exposure assessment, and toxicity assessment. For the streamlined evaluation of the potential threat to human health, COCs are identified from the list of COPCs, assuming a certain mass of these COPCs within the buildings, their potential for release and/or migration as the buildings deteriorate, and the inherent toxicity of the constituents. Likewise, the exposure pathways of concern are identified as a result of the typical contribution of the pathways when risk is quantified. However, the cumulative impact of these uncertainties is low since the list of COCs includes the high mass, high concentration constituents known to have been used at PORTS, coupled with the fact that such constituents are present in the environmental media within the quadrants.

The results of the streamlined evaluation of the threats to human health provide information necessary to justify action at PORTS (as related to the expected waste to be generated) and allow the evaluation and selection of the best remedy for PORTS.

5.2 POTENTIAL THREAT TO ECOLOGICAL RECEPTORS

This streamlined ecological risk evaluation is being conducted using the PORTS-specific guidance *Methods for Conducting Ecological Risk Assessments and Ecological Risk Evaluations at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2013c). This section uses the results of existing ecological assessments to determine the likelihood of impacts to ecological receptors as a result of contaminants that may be released from degrading buildings.

5.2.1 Process to Qualitatively Evaluate Potential Threat to Ecological Receptors

Seven steps are identified in the PORTS-specific guidance for conducting an ecological risk assessment. Using existing assessments of ecological impacts from PORTS activities, the screening elements (Steps 1 and 2) and problem formulation (Step 3) were completed when developing the waste disposition PER (DOE 2010a) and waste disposition RI/FS Work Plan (DOE 2012a) for this project. The PER concluded that no new data were required to qualitatively assess ecological risk. Therefore, no new field sampling design (Steps 4 and 5) or data analysis (Step 6) was performed to evaluate impacts of the no-action alternative to ecological receptors. Only Step 7 remains, and it is risk characterization. To complete this step qualitatively, the evaluation of COPCs developed in Section 5.1.1 will be examined against the assessment endpoints identified in previous ecological evaluations to determine if future impacts are expected. These endpoints from past evaluations are discussed in Section 5.2.2.

5.2.2 Receptor Identification and CSM Development

As part of the RFI at PORTS, DOE performed an assessment of the impacts that releases from PORTS had or may have had to the ecological receptors on the PORTS reservation. The results were reported in *Baseline Ecological Risk Assessment, Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 1996f). The PORTS Baseline Ecological Risk Assessment (BERA) focused on the Little Beaver Creek and Big Run Creek watersheds, and the northwestern, western, and southwestern tributaries. The Little Beaver Creek watershed runs primarily through Quadrants II and IV. Big Run Creek is located mostly in Quadrant I. The northwestern and western tributaries are mostly impacted by contaminants from Quadrant III, whereas the southwestern tributary is impacted by those from Quadrant I.

The endpoint species for the BERA included: aquatic species, including fish and benthic macroinvertebrate communities; terrestrial species, including vascular plants, soil invertebrates, vole, short-tailed shrew, American woodcock; and piscivorous species, including belted kingfisher and mink. Wetlands and T&E species were also addressed. However, no T&E species were identified on the PORTS reservation in the BERA, and there was negligible risk to the wetland vegetation present. A CSM was developed for the PORTS BERA exposure pathways (Figure 5.3), and it shows how wastes from PORTS move through environmental media to receptors. The existing CSM is sufficient for the needs of this streamlined evaluation of threats to ecological receptors.

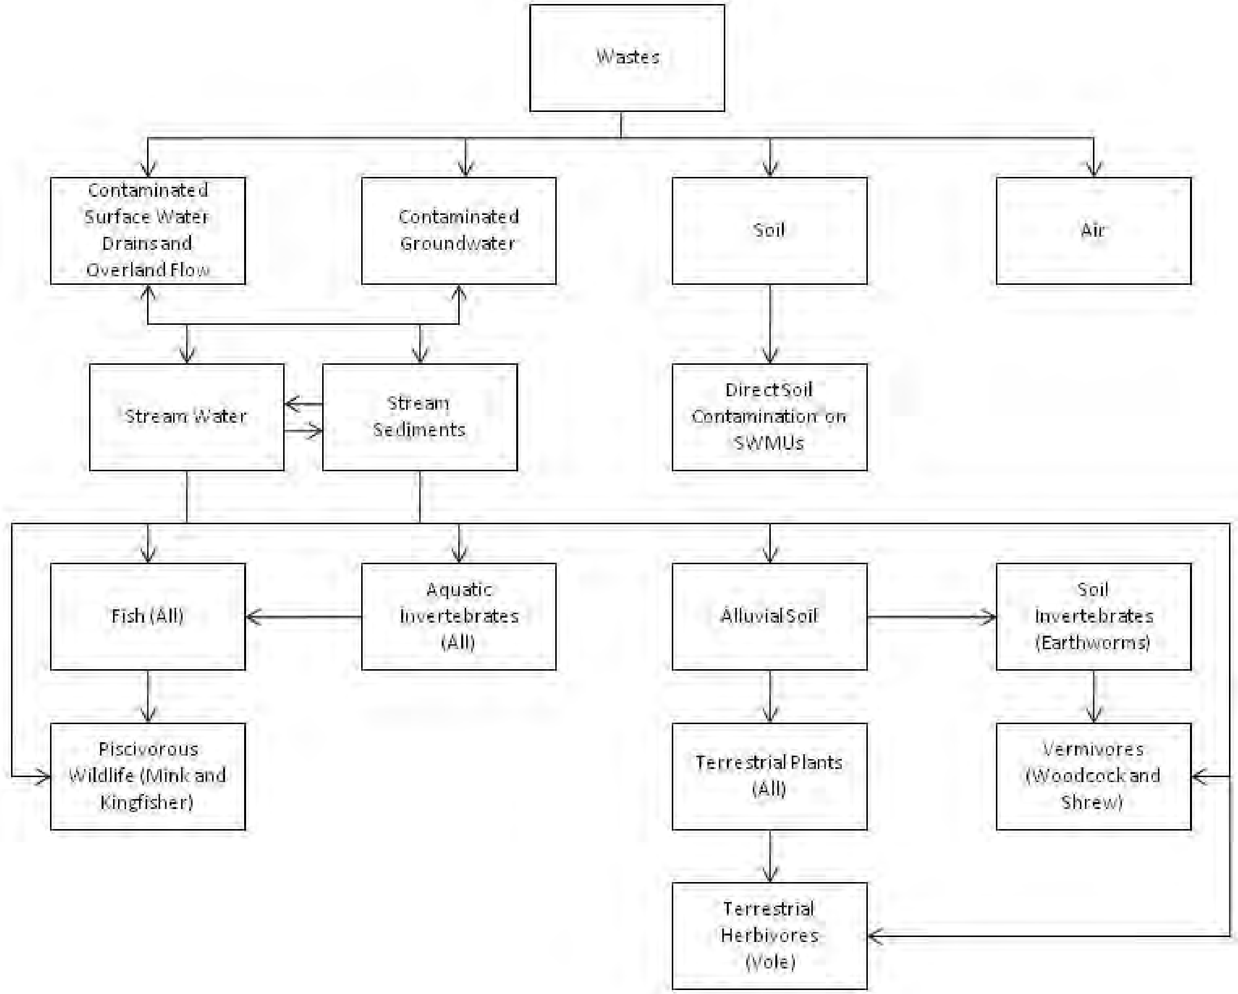

Figure 5.3. CSM for PORTS BERA Exposure Pathway

5.2.3 Risk Characterization

The results of the BERA are presented in this section. These results illustrate which contaminants have historically had the potential to impact ecological receptors at PORTS, based on concentrations in environmental media. Below is a summary of the BERA.

The risk results, presented in the BERA, from the Little Beaver Creek (Quadrants II and IV) watershed indicate potential impacts from chromium and mercury contamination to the invertebrate community in its alluvial soils. Although there were no risks to plant communities from contaminated alluvial soils, contaminants may bioaccumulate and pose a risk to herbivorous wildlife. Potential impacts to the wildlife communities were also concluded. PCBs were found in sufficient amounts to have potential adverse impacts on the abundance and reproduction of the shrew population through ingestion of earthworms and incidental ingestion of soils. These mammals have small home ranges and are likely impacted from distinct areas of contamination. In addition, the BERA concluded that the American woodcock may be impacted by the presence of chromium and the ingestion of earthworms at Little Beaver Creek. The BERA also concluded that all other endpoint species were unlikely to have impacts from PORTS contaminants.

For Quadrants II and IV, the COCs identified in the BERA were chromium, mercury, and PCBs. Sufficient quantities of these contaminants may remain in buildings and therefore would be present in the associated waste in these quadrants, enough to cause increased impacts to receptors if they are released and migrate to associated exposure media. As discussed above, it is likely that PCB concentrations in the on-PORTS environment would increase from buildings in these quadrants in the future if no action is taken on the buildings and associated waste. Wildlife communities could be impacted from future releases. Chromium and mercury concentrations are also likely to increase as the buildings degrade and release contaminants. Therefore, based on PORTS operations and the likelihood of further releases of these contaminants into the environment in sufficient quantities, chromium, mercury, and PCBs are identified as COCs for this qualitative ecological risk assessment.

No unacceptable risks from past operations were identified in the BERA for ecological endpoints in the Big Run Creek watershed (northwestern or western tributaries). There were indications of zinc toxicity impacts to the alluvial soil plant communities in the southwestern tributary (Quadrant I). Zinc was not identified as a COPC from buildings within this quadrant. Based on these results, it is unlikely that further releases from buildings or waste would impact ecological receptors. No ecological COCs from Quadrants I and III are identified.

The results of this qualitative evaluation of threats to ecological receptors indicate that there are potential impacts to on-PORTS ecological receptors from the no-action alternative.

5.3 RISK ASSESSMENT DATA LIMITATIONS AND RECOMMENDATIONS FOR FUTURE WORK

Little quantitative sampling data are available on contamination levels in anticipated building waste. Therefore, a full quantification of the baseline risk to humans and ecological species as a result of building degradation and not disposing of wastes is not possible. However, even if additional sampling data were available, there would be great uncertainty with estimating the rate of degradation, rate of contaminant release, and rate of contaminant migration to receptors. The analysis presented in this section demonstrates that potential threats to humans and ecological species can be described qualitatively by using the existing process knowledge and limited sample data from the PGE. For the no-action alternative, no additional data are needed to assess future threats to humans or the environment, and no future risk assessment work in that regard is recommended.

5.4 REVISED RAOS

As a result of evaluating the no-action alternative scenario described within the streamlined risk assessment, DOE concludes that active measures are necessary to protect public health or welfare and the environment from actual or threatened releases of pollutants or contaminants from PORTS. Such releases may present an imminent and substantial endangerment to the public health and the environment. The assessment shows radionuclides and other contaminants such as PCBs, asbestos, TCE, and chromium may be a future threat to on-PORTS users under no action. The RAOs developed during project scoping addressed the concern of unacceptable toxicity and carcinogenicity.

There is the limited potential, albeit slight, for future risk to terrestrial ecological populations if the buildings are left to degrade. To be protective of ecological species, the RAOs presented during project scoping have been revised to provide for future ecological protection. These RAOs are presented in Section 7.3.

HIGHLIGHTS OF SECTION 5

- With no waste disposition option, degrading buildings could pose an unacceptable future risk to on-PORTS users and limited terrestrial ecological species.

- With no D&D or waste disposition option, degrading buildings could pose some future off-PORTS unacceptable risk; however, because of limited contaminant migration these risks are expected to be less than on PORTS.

- The potential for future threats to human health to on-PORTS receptors and the environment from no waste disposition indicates the need to take an action to remedy the threat.

NEXT STEP: SECTION 6 SUMMARIZES THE PROBLEM STATEMENT

TO PREPARE FOR IDENTIFYING SOLUTIONS

6. SUMMARY OF PROBLEM STATEMENT

The intent of Section 6 is to present a summary of the problem statement for the Site-wide Waste Disposition Evaluation Project. A problem statement is developed from understanding the CSM. A CSM answers three questions: (1) what is the source of contamination (the source term), (2) how do contaminants move through the environment (transport pathways), and (3) how are potential human and ecological receptors exposed to the contamination (receptor exposure). Section 6 is organized around those elements of the CSM. Then, to put the problem into perspective, the magnitude of the threat associated with leaving the waste behind is provided.

This section is important because a solid understanding of the problem is needed before solutions are considered and alternatives are developed.

6.1 SOURCE TERM

Demolition of the process buildings, support structures, and other facilities at PORTS is anticipated to generate 1.47 million cy of various types of waste (RC-1, EC-1 and EC-2). Of that, an estimated 53,000 cy of residual soil (RC-1, EC-1) is estimated to be generated during D&D activities. Small waste streams such as fluorescent light bulbs would be removed prior to demolition for regulation-driven disposal, regardless of the final waste disposition decision. Of this total volume, an estimated volume of 110,000 cy of material may be recycled and/or reused. Of the remaining waste streams, the majority is anticipated to be classified as LLW.

Also included in this source term is any non-D&D waste (RC-2) generated because it is a potential waste stream. Some non-D&D waste (RC-2, EC-1) may be able to be used as fill if it meets the performance standards for fill, which will be set forth in more detail in remedial design documentation and if additional regulatory approval is obtained to excavate and place such non-D&D waste (RC-2) in a potential OSDC and use it as fill. Additionally, the impacts and implications of up to an estimated 710,000 cy of Ohio Consent Decree waste (RC-2) from the remaining environmental cleanup activities are considered, although additional regulatory approval would be necessary for excavation and placement of such Ohio Consent Decree waste in a potential OSDC. The 710,000 cy is an estimate established for the purposes of conducting a complete and thorough evaluation of the alternatives. The actual volume of any Ohio Consent Decree waste (RC-2) will be determined based on several factors, including the final remediation decision associated with such media. The decision to excavate or dispose of Ohio Consent Decree waste (RC-2) is not being made under this project. The source contaminant description as described in Section 4 of the RI/FS is the same for all of these waste streams (RC-1, RC-2).

The scope of other actions, besides those taken pursuant to the Ohio Consent Decree, that would generate non-D&D waste (RC-4) have not been identified yet, so there are no estimated volumes included in this RI/FS. The volume of fill required is estimated to be twice the volume of any waste with void spaces (EC-2) (which includes concrete, asbestos, PGE, and other building waste as defined in Section 4).

Historical sampling efforts at ETTP indicate the types of contamination that may be found in the larger buildings at PORTS. These contaminants would also be found in residual soil (RC-1, EC-1), Ohio Consent Decree soils (RC-2, EC-1), and other sources of contaminated fill (RC-3). There is the potential for multiple contaminants, but technetium-99 and the uranium isotopes are the most prevalent and serve as good bases for comparison between buildings and waste streams. Table 6.1 presents a side-by-side comparison of the various expected contaminants in some of the larger or more contaminated waste streams. The ETTP results are from a statistical calculation that gives the expected concentrations with a certain degree of confidence and reflects typical conditions of the associated building structures (no equipment). The X-326 converter results are maximum concentrations found to date (not all from the same sample) that represent a worst case condition. Soil background levels at PORTS are also presented as a reference and are considered to be provisional because work is underway to finalize the soil background levels (DOE 1996e). The data supporting concentrations in the process equipment are from PORTS sampling of the process equipment and various deposits associated with it. Sampling is ongoing, and the results from these samples are not yet representative of the entire PGE waste stream. The results presented for three of the larger buildings are like those from buildings at ETTP. The ETTP buildings are older and likely have higher levels of contamination than those that will be found in the PORTS buildings. However, these data do provide decision makers with a basis for understanding the level of contamination that may be found in the larger waste streams. This leads to a key conclusion. For the most part, the levels of radioactivity in the waste streams at PORTS are fairly low as shown in the ETTP building structure results, although small volumes of waste could contain fairly elevated levels, as can be seen from the maximum concentration found to date in the X-326 converters.

Table 6.1. Comparison of Radioactivity in Potential Waste Streams at PORTS

Radionuclide	Soil Background[a] (pCi/g)	X-705 (Represented by K-1420 at ETTP) (Expected-pCi/g)	X-720 (Represented by K-1401 at ETTP) (Expected-pCi/g)	X-330 (Represented by K-29 at ETTP) (Expected-pCi/g)	X-326 Converters (Max-pCi/g)
Tc-99	ND	213	14	300	166,000
U-233/234	1.68	274	18	84	33,170
U-235	0.076	20	1.4	4.6	1,007
U-238	1.64	167	17	20	623

DOE = U.S. Department of Energy
ETTP = East Tennessee Technology Park
ND = none detected

6.2 TRANSPORT PATHWAYS

Under no action, buildings and structures with this contamination would be allowed to degrade. Any buildings that have been demolished would remain as a pile of waste.

Technetium-99 is highly soluble and mobile, and it has been found at high concentrations in PORTS groundwater. Uranium isotopes are not as soluble, adsorbing onto soil particles. PCBs likewise are not soluble, but many of the organic compounds (especially the VOCs) are quite soluble and mobile. With the introduction of rain, many of the mobile contaminants would move from the waste into the surrounding soil and underlying groundwater. The less mobile contaminants may still leave the waste and repartition on the surface soil.

Although groundwater conditions in that area of the facility tend to be unfavorable for significant migration of contaminants off PORTS, there has been historical off-PORTS groundwater contamination that is currently controlled with containment systems. The groundwater flow system at PORTS includes the aquifers of the Berea sandstone and the unconsolidated Gallia sand and gravel, along with the aquitards of Sunbury shale, Cuyahoga shale, and unconsolidated Minford clay and silt. The basal portion of the Minford is generally grouped with the Gallia to form the uppermost and primary aquifer at the facility. The Gallia sand averages 3 to 4 ft in thickness across the plant and is characterized as reddish-brown, clayey, medium-to-coarse sand and gravel (sand and gravel are typically poorly sorted). Groundwater flow at PORTS, at least within the Gallia, can generally be divided into four separate flow regions. The groundwater flow divides and general directions of groundwater flow in the Gallia and Berea aquifers generally coincide with topographic highs along the center of the industrial complex (from south to north) and subtle topographic highs radiating outward and separating the predominant surface water features draining the facility.

Natural recharge to the groundwater flow system comes mainly from precipitation, although land use and the presence of thick upper Minford clay effectively reduce recharge to underlying units. Discharge of groundwater to the surface occurs primarily along streams that transect and border the facility.
Four creeks, or drainage channels, drain the facility. The four creeks and drainage ditches dissect the unconsolidated Minford and Gallia members, as well as the upper bedrock units (Sunbury shale and Berea sandstone), resulting in the discharge of groundwater to them. Groundwater flow beneath PORTS is generally toward one of these discharge locations, which in most cases, limits any groundwater off-PORTS migration of PORTS contaminants.

6.3 RECEPTOR EXPOSURE

PORTS is set in a rural area. In the immediate area surrounding PORTS, land is used primarily for farms, pastures, forests, and rural residences. At PORTS, Perimeter Road surrounds a 1,000-acre centrally developed industrial area. The portion of the plant outside of Perimeter Road has approximately 2,500 acres of land that include a water treatment plant, holding ponds, landfills, storage yards, parking areas, open fields, and forested buffer areas. The most likely future receptors of exposure from contamination in potential waste streams are the future users of the industrialized area of the plant. Because of the current use of the plant and the rural nature of the surrounding area, an on-PORTS industrial worker is the most likely receptor. However, it is conceivable that a future rural resident could access the plant. Because of the limited opportunity for off-PORTS migration of contamination, current off-PORTS receptors are not likely to receive contamination exposure from future waste streams. Current on-PORTS receptors are well protected under existing DOE policies.

Because of the land use, there is some potential for terrestrial species to access the plant and future buildings or waste streams. However, the industrial plant is not a current suitable habitat for large populations of terrestrial species. There could be some threat to individual members of an ecological species on the plant, but impacts to entire populations are expected to be minimal because of the industrial nature of the plant.

6.4 THREAT TO HUMAN HEALTH AND THE ENVIRONMENT

The process buildings, complex facilities, and supporting facilities contain numerous radiological and chemical contaminants that are known carcinogens and/or toxicologically hazardous substances. Under the potential future scenarios where a trespasser, an industrial worker, a resident, or ecological receptor unknowingly comes in contact with this contamination, it is likely that the threat to human health and the environment would exceed EPA recommended levels. In addition, the degrading buildings and any resultant waste piles would be a physical threat.

6.5 NEED FOR ACTION

As the buildings degrade, piles of waste (RC-1) would form. Without an acceptable disposal outlet, these piles could cause an unacceptable threat to human health. Therefore, a solution is needed to provide a Site-wide, protective, regulatory-compliant waste disposal option.

HIGHLIGHTS OF SECTION 6

- D&D waste volume generated under the DFF&O (RC-1) to be considered is 1.47 million cy.
- Up to an estimated 710,000 cy of non-D&D waste (RC-2) are also evaluated.
- Waste (RC-1, RC-2) contains radionuclides, VOCs, SVOCs, metals, and PCBs as well as ACM. Numerous waste types and waste streams are present.
- Contaminants from uncontrolled waste are unlikely to migrate off PORTS assuming existing groundwater extraction systems remain in place.
- Waste is a physical hazard if left in place and could contaminate media as a result of weathering.
- The most contaminated waste stream is likely to be the deposits in the process equipment. This stream could contaminate on-PORTS soil and groundwater to unacceptable levels, if not controlled.
- The potential for a future unacceptable threat to human health and the environment provides the basis for taking action to remedy the threat.
- The problem is well understood, and protective and compliant solutions can be developed.

NEXT STEP: SECTION 7 SETS THE FOUNDATIONAL ELEMENTS TO ALLOW THE DEVELOPMENT OF ALTERNATIVES

7. PRELIMINARY IDENTIFICATION AND SCREENING OF WASTE DISPOSITION ALTERNATIVES

7.1 INTRODUCTION

Once the problem statement has been identified, potential solutions are developed. The intent of Section 7 is to provide the foundation for developing solutions. This section does not develop the alternatives, but it identifies all of the considerations that will be factored into the alternative development in Section 8. First, regulations that need to be considered in developing alternative solutions are provided in Section 7.2. Section 7.3 then takes those requirements, considers other regulatory issues, and assesses the level of protection the alternatives must meet, thereby developing the objectives of the remediation effort – RAOs. The last element of the foundation for alternative development is to identify potential technologies to be considered in the development of alternatives. This section, Section 7.4, is structured in accordance with CERCLA guidance to describe GRAs and technology types available, provide a preliminary screening of technology types and process options, and then evaluate and identify representative process options to use to describe and evaluate alternatives. Development of the remedial alternatives then occurs in Section 8 by using the results in this section. Section 7 concludes with a presentation of potential WAC for the representative disposal locations under consideration (Section 7.5).

7.2 CHEMICAL- AND LOCATION-SPECIFIC ARARS/TBCS

To develop objectives and goals of remediation and to develop alternatives, the requirements of federal and state regulations that apply or are relevant and appropriate (called ARARs) to the problem at hand must be identified and understood. Entirely on-Site remedial actions are required to attain ARARs, unless specific ARARs are waived in accordance with CERCLA. The ARARs include only federal, state, and local environmental or facility siting laws/regulations; they do not include occupational safety or worker radiation protection requirements. Additionally, per the DFF&O and 40 *CFR* 300.400(g)(3), substantive requirements of other advisories, criteria, or guidance that are not ARARs are to be considered in determining remedies (TBC guidance). ARARs and TBCs are identified for the waste disposition remedial action that includes both on-Site waste disposal and off-Site waste disposal.

Section V, General Provisions, paragraph 9.a of the DFF&O provides that portions of response actions "conducted entirely on site pursuant to Work Plans or plans concurred with or approved by Ohio EPA under these Orders can also be, at Respondent's discretion, conducted pursuant" to Section 121(e)(1) of CERCLA, 42 *United States Code* Section 9621. Section 121(e)(1) specifically provides that no federal, state, or local permit shall be required for the portion of any removal or remedial action conducted entirely as an on-Site response action. In addition to permits, EPA has interpreted this section broadly to cover all administrative provisions from other laws, such as recordkeeping, consultation, and reporting requirements. In other words, administrative requirements do not apply to response actions that occur entirely on Site (EPA 1998). Therefore, only the substantive requirements in the ARARs and TBCs in Appendix F apply to response actions occurring entirely on Site. Those portions of the remedial action that occur off Site are subject to both the substantive and administrative requirements of applicable laws.

ARARs/TBCs are typically divided into three groups: (1) chemical-specific, (2) location-specific, and (3) action-specific. Pursuant to EPA guidance, there are no ARARs/TBCs for a no-action alternative (EPA 1991). No chemical-specific ARARs/TBCs were identified for the two action alternatives. A brief description of key location-specific ARARs/TBCs follows. A brief discussion of action-specific ARARs/TBCs is provided in Section 8.2 along with any justification for a waiver. A detailed discussion of all ARARs and TBCs specific to this response action is included in Appendix F to this RI/FS report.

7.2.1 Chemical-specific ARARs/TBCs

Chemical-specific ARARs/TBCs provide health- or risk-based concentration limits or discharge limitations in various environmental media (surface water, groundwater, soil, and air) for specific hazardous substances, pollutants, or contaminants. Because the Site-wide Waste Disposition Evaluation Project is not addressing cleanup decisions for contaminated environmental media, no chemical-specific ARARs and TBCs were identified.

7.2.2 Location-specific ARARs/TBCs

Location-specific requirements establish restrictions on permissible concentrations of hazardous substances or establish requirements for how activities will be conducted because they may occur in special locations (e.g., wetlands, floodplains, critical habitats, streams). Location-specific ARARs and TBCs were identified for the protection of wetlands, aquatic resources, endangered species, and cultural resources at candidate locations under the on-Site disposal alternative.

A number of location-specific siting restrictions and considerations were also identified. They would impact where and how an on-Site disposal facility could be constructed as part of an on-Site waste disposal action. These requirements, which are not triggered unless an action is taken to construct an on-Site disposal facility, are addressed in detail as action-specific ARARs/TBCs in Appendix F.

7.2.2.1 Floodplains and wetlands

Wetlands, floodplains, and aquatic resources are present at PORTS. The proposed potential OSDC location is not within a 100- or 500-year floodplain, and none of the planned activities are expected to impact floodplain areas. Six wetlands, including jurisdictional wetlands, have been identified that may be affected by construction activities (Study Area D); the acreages for these wetlands are given in Table D.6 in Appendix D. These wetland and aquatic resources would be appropriately protected or mitigated in accordance with the location-specific ARARs and TBCs identified in Table F.1, as appropriate. DOE is evaluating impacts of the proposed actions for potential adverse effects to wetlands and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

7.2.2.2 Threatened and endangered species

A PORTS-wide T&E species survey, which was completed in 1996, identified a number of potentially suitable habitats at PORTS for federal- and State of Ohio-listed T&E species, although only one state-listed plant species was actually observed (LMES 1997). The locations of the identified habitats and plant species were thought to be well outside of the areas identified under the on-Site waste disposal remedial alternative action. A more recent study (Ohio University 2012), however, noted federal-listed Indiana Bat habitat as being more widespread than previously mapped, including the mature forest areas in Study Area D.

7.2.2.3 Cultural resources and mitigation of impacts

Cultural resources include any prehistoric or historic district, site, building, structure, or object resulting from, or modified by, human activity. Under federal regulations (36 *CFR* 800), federal agencies must assess the impacts their actions have on historic properties and, if appropriate, avoid, minimize, or mitigate adverse effects. Historic properties are cultural resources listed in, or eligible for listing in, the NRHP because of their significance and integrity.

Construction of a potential OSDC would have direct effects on areas of PORTS outside of Perimeter Road. Two areas are being evaluated as potential locations for a potential OSDC. OSDC Study Area D is located in the northeast corner of PORTS (see Figure 3.12). OSDC Study Area C is located on the eastern edge of PORTS, closer to the southern DOE boundary. OSDC Study Area D has been identified as the representative location for purposes of the RI/FS. The project area for this proposed action includes areas throughout PORTS because of the potential for the construction of haul roads or borrow areas for fill. Based on the results of the architectural inventory and the Phase I and II archaeological surveys of the DOE reservation, a number of potential historic properties have been identified.

As a result of the surveys of the OSDC Study Areas, three sites were identified in Archaeological Study Area 2 for further investigation. No sites were identified in Archaeological Study Areas 1 and 3. Each of the three sites required further study (a Phase II investigation) to determine eligibility for the NRHP. Two of the sites have been recommended as eligible for listing on the NRHP as a result of the Phase II investigation, and if they would be adversely affected by siting of a potential OSDC, potential mitigation measures would be developed. DOE is evaluating impacts of the proposed actions for potential adverse effects to historic properties and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

DOE is working closely with Native American Tribes, OHPO, the Advisory Council on Historic Preservation (ACHP), and the public with an interest in historic preservation to identify appropriate mitigation measures to comprehensively address D&D as well as waste disposition activities at the Site. In the last several years, multiple meetings were held with the Site-specific Advisory Board (SSAB) and the public, and included updates on NHPA activities and opportunities for interested parties to provide input to DOE. Interaction with Native American Tribes, OHPO, ACHP, SSAB, and the interested public will continue to identify and refine potential mitigation measures for PORTS.

7.3 RAOS

RAOs are developed during the RI/FS process to set goals that ensure the protection of human health and the environment. The RAOs established for the waste disposition RI/FS are the following:

- Prevent uncontrolled storage or staging of waste piles. Waste generated from demolishing structures at PORTS (RC-1) or from the natural degradation of the structures must be disposed in compliance with the substantive provisions of the ARARs/TBCs in Appendix F.

- Implement the final disposition of wastes (RC-1) in a manner that ensures human and ecological receptors are protected from radiological and nonradiological contaminants. For an on-Site alternative, the RAO is satisfied by developing WAC that eliminate human exposures to contaminants that exceed a human health risk of 1×10^{-5} cumulative excess lifetime cancer risk (ELCR) or a cumulative hazard index (HI) of 1. For an off-Site alternative, the RAO is satisfied by meeting the representative off-Site facility’s approved WAC.

- Control the migration of contaminants from the wastes (RC-1) that could cause adverse groundwater and surface water impacts. For an on-Site alternative, the RAO is satisfied through the development of WAC that prevent the migration of contaminants that would cause an exceedance of ambient water quality criteria in surface water and MCLs in groundwater (at the waste boundary) for a performance period of 1,000 years. For an off-Site alternative, the RAO is satisfied by meeting the representative off-Site facility’s approved WAC.

For both the on-Site and off-Site alternatives, WAC are specifications and conditions under which waste can be accepted for disposal, and they include regulatory standards, facility design information, and risk-based analyses performed over an approved facility performance period. WAC for all waste storage, treatment, or disposal facilities, operations, and activities specify, at a minimum, the following:

(a) Allowable activities and/or concentrations of specific contaminants

(b) Acceptable waste form and/or container requirements that ensure the chemical and physical stability of waste under conditions that might be encountered during transportation, storage, treatment, or disposal

(c) Restrictions or prohibitions on waste, materials, or containers that may adversely affect waste handlers or compromise facility or waste container performance.

7.4 INITIAL IDENTIFICATION AND PRELIMINARY SCREENING OF WASTE DISPOSITION ALTERNATIVES

The GRAs, remedial technologies, and process options considered for alternative development in this FS are identified in this section. These technologies and process options were identified from similar efforts at the Fernald Plant and the Oak Ridge Reservation where site-wide disposal decisions have been implemented. Although these FSs were conducted in the 1990s, there have not been significant changes in the technologies associated with transportation and disposal since that time. The scope of the evaluation would be from transporting waste, generated under separate evaluations, through ultimate disposal of the waste.

Most treatment of waste is addressed in the documents with actions that generate waste (such as the process building RI/FS). These generating projects are responsible for ensuring that the waste created meets transportation and disposal requirements. Centralized treatment process options that prepare waste for disposal or reduce the volume of waste are, however, considered in this waste disposition RI/FS evaluation. Technologies for demolishing buildings, packaging waste, removing environmental media, or treating environmental media are not included in this technology screening.

The technologies and process options are first screened for technical implementability at PORTS. Technologies and process options retained after this initial screening are then evaluated with respect to effectiveness, implementability, and cost. Those that best represent a GRA or technology are then used to describe the waste disposition remedial alternatives in the next section. The criteria are described as follows:

- Effectiveness—This criterion is the primary one for consideration of process options. This evaluation focuses on the potential effectiveness of the process option in handling the volumes of waste and meeting the RAOs, as well as the potential impacts to human health and the environment during implementation. The reliability of the process options with respect to the contaminants and conditions at the site should also be a factor in the evaluation.

- Implementability—Implementability is the measure of technical feasibility, including constructability and maintainability; administrative feasibility to construct, operate, and maintain the remedial action alternative; and the availability of services and materials to implement the alternative. This includes the availability and capacity of treatment, storage, and disposal facilities; equipment; design; and operating/support personnel.

- Cost—Cost plays a limited role in the screening of process options. Relative capital and S&M costs are used rather than more detailed cost estimates. At this stage, the cost analysis is made on the basis of engineering judgment using a high, medium, or low comparative cost scale. Any supporting cost estimates are only used to screen process options and are not part of any alternative evaluation in subsequent sections.

7.4.1 Identification of General Response Actions

The GRAs describe actions, alone or in combination, that would satisfy the RAOs. The following GRAs apply to the development of waste disposition alternatives for the D&D waste (RC-1):

- No Action
- Institutional Controls
- Centralized Treatment
- On-Site Disposal
- Off-Site Disposal
- Recycling and/or Reuse
- Waste Transportation.

The term GRA refers to a general category of measures that produce similar results when implemented. The following list of GRAs, which would achieve the RAOs, has been generated for each medium of concern:

- No Action – In the FS, the no-action scenario is considered to be the baseline to which other remedial alternatives are compared and is retained throughout the FS process. This is required by the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), regardless of its effectiveness in achieving the RAOs.

- Institutional Controls – These include various access restrictions and/or land-use restrictions to reduce or eliminate exposure pathways related to direct human contact with contaminated media.

- Centralized Treatment – This includes physical, chemical, and thermal measures that would reduce the toxicity, mobility, or volume of a waste stream by altering its physical or chemical properties, implemented as a centralized system. A centralized treatment system is defined as one that is used by multiple projects or decisions prior to disposal or recycling and/or reuse. Centralized treatment options are included in this waste disposition RI/FS. In addition, if any material is produced from the operation of a potential OSDC that requires treatment, centralized treatment may be used to allow that material to be disposed in a potential OSDC. Treatment of contaminated leachate, decontamination water, or storm flow from cell operations or treatment of contaminated fill material are two examples of such material.

- On-Site Disposal – This includes placement of D&D waste (RC-1) in an existing, if available, or new on-Site permanent engineered disposal facility, which restricts contaminant migration and mitigates exposure routes. This technology controls exposure pathways to human or ecological receptors associated with a contaminated material and controls migration of the contaminants into the environment. Also included are various options for providing fill for operating a new on-Site disposal facility.

- Off-Site Disposal – This GRA includes placement of D&D waste (RC-1) in an existing or new off-Site permanent engineered disposal facility, also restricting contaminant migration and exposure off of PORTS.

- Recycling and/or Reuse – This GRA includes the beneficial reuse of a material either directly or after decontamination, or by recycling its construction materials.

- Waste Transportation – This GRA includes technologies that are used to transport D&D waste (RC-1) to the selected disposal location, as well as any additional packaging that may be needed to control releases of contamination during the transportation effort.

7.4.2 Identification and Screening of Remedial Technology Types and Process Options

The next step in the alternative development process is to identify and screen process options for each technology type. A process option refers to a specific process within each technology type. The result of this section will be a list of process options that will be used to describe and evaluate alternatives. As specified in EPA RI/FS guidance (EPA 1988), two steps are taken to reduce the number of process options associated with each GRA that undergoes detailed analysis. In the initial screening step, each process option is evaluated to determine whether it is technically applicable to the remediation location(s). To determine technical applicability, the capabilities of each process option are evaluated against site conditions, and the expected contaminant types and concentrations. Process options that are not technically applicable to the site or waste are eliminated from future consideration. Process options that are clearly administratively impractical are also eliminated. In the second screening step (Section 7.4.3), the retained process options are evaluated more closely to select one or more process options for each technology type. The process option that best satisfies the evaluation criteria is identified as the representative process option for assembly with other process options and used to provide a detailed description and evaluation of alternatives. Selection of representative process options for the description of alternatives does not eliminate other process options from future consideration.

The technology types and process options identified for each GRA and the results from process options screening for technical applicability are depicted in Figure 7.1. The “Screening Comments” column in Figure 7.1 identifies the retained process options, based on technical applicability to site conditions and/or waste types, and describes the process options that were screened out. Those process options that are applicable are described below. Process options are identified for both primary waste streams (those generated directly as a result of potential demolition or cleanup activities) that were identified earlier as the scope of this decision and for secondary waste streams from implementing a disposal action.

Secondary waste streams can originate from activities to decontaminate, treat, transport, or dispose of the primary waste streams. They typically consist of PPE and wastewaters.

7.4.2.1 No Action

Under the No-Action GRA, no coordinated effort would be implemented to manage future generated waste. The no-action process option establishes a baseline for comparison with other GRAs.

7.4.2.2 Institutional controls

Access and land-use restrictions, as well as maintenance and monitoring, are institutional controls that could reduce the potential for exposure to waste placed in a potential on-Site disposal facility. These technologies and the associated process options are considered to be technically implementable and would be used in conjunction with on-Site waste disposal process options.

Access and Use Restrictions

Physical Barriers/Security. Fences, signs, buffer zones, or other barriers can be installed around potential waste disposal and support areas to limit access. Security measures (e.g., guards, surveillance) can be used to limit access to waste disposal areas.

Covenants and Deed Restrictions. Environmental restrictions on a property’s deed can be used to restrict use of real property to ensure protectiveness of a selected remedial action.

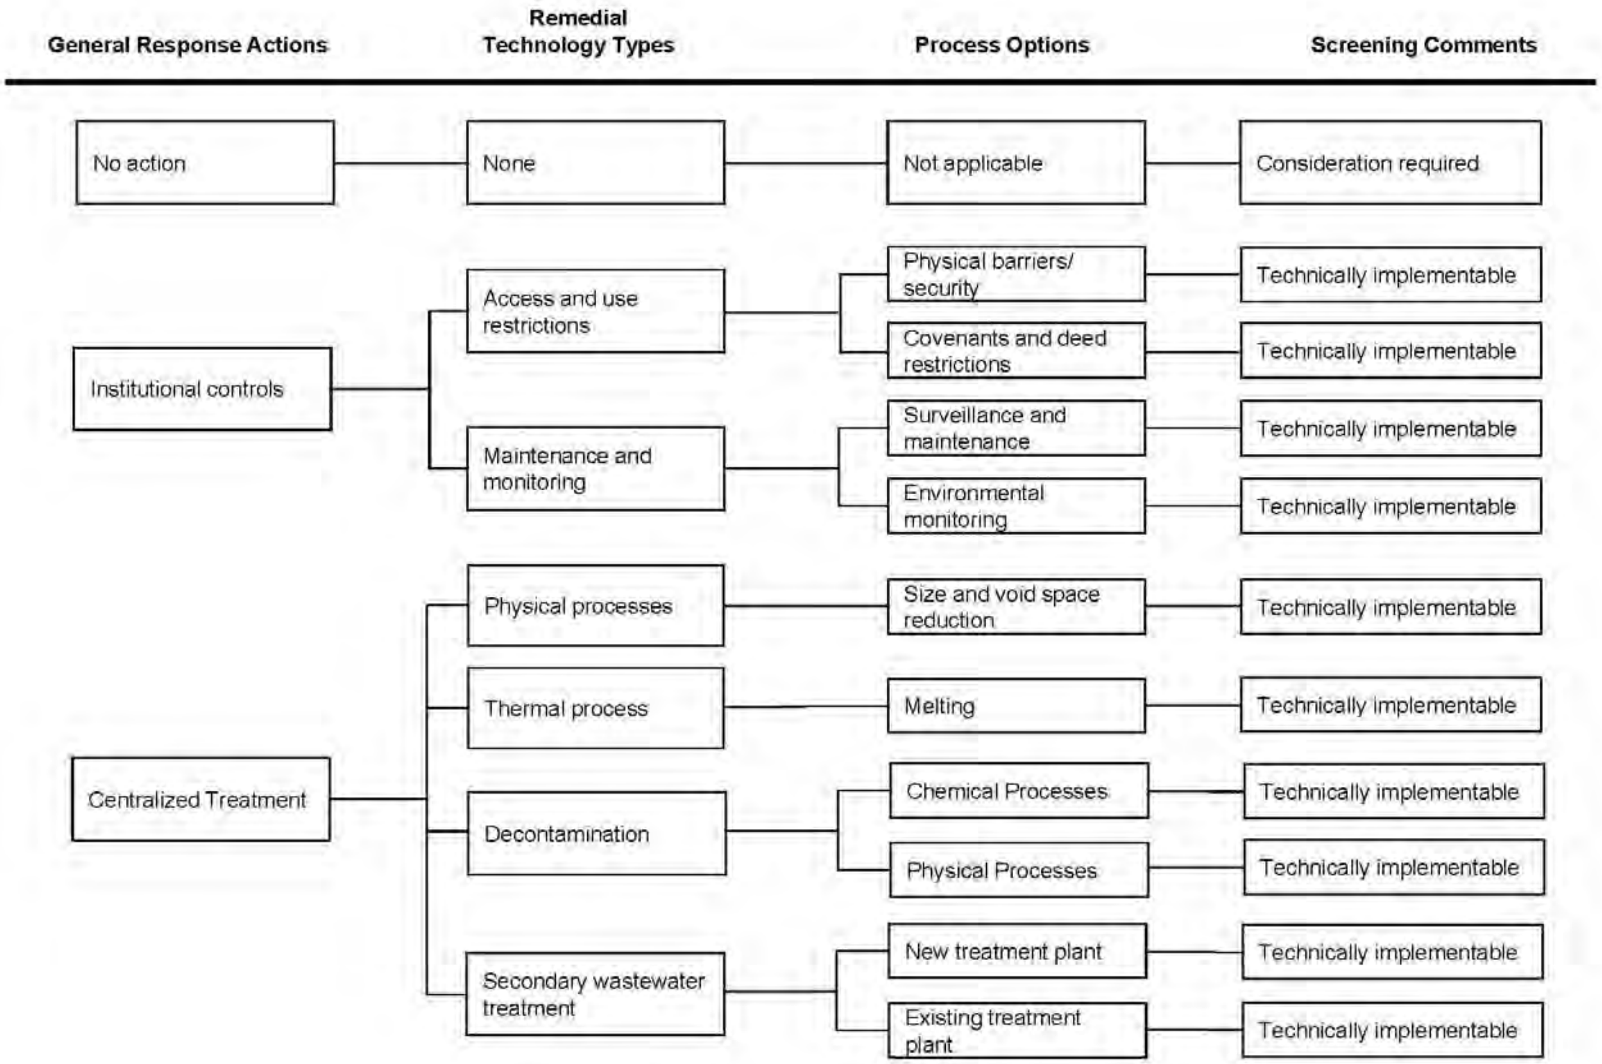

Figure 7.1. Screening of Remedial Technology Types and Process Options for PORTS

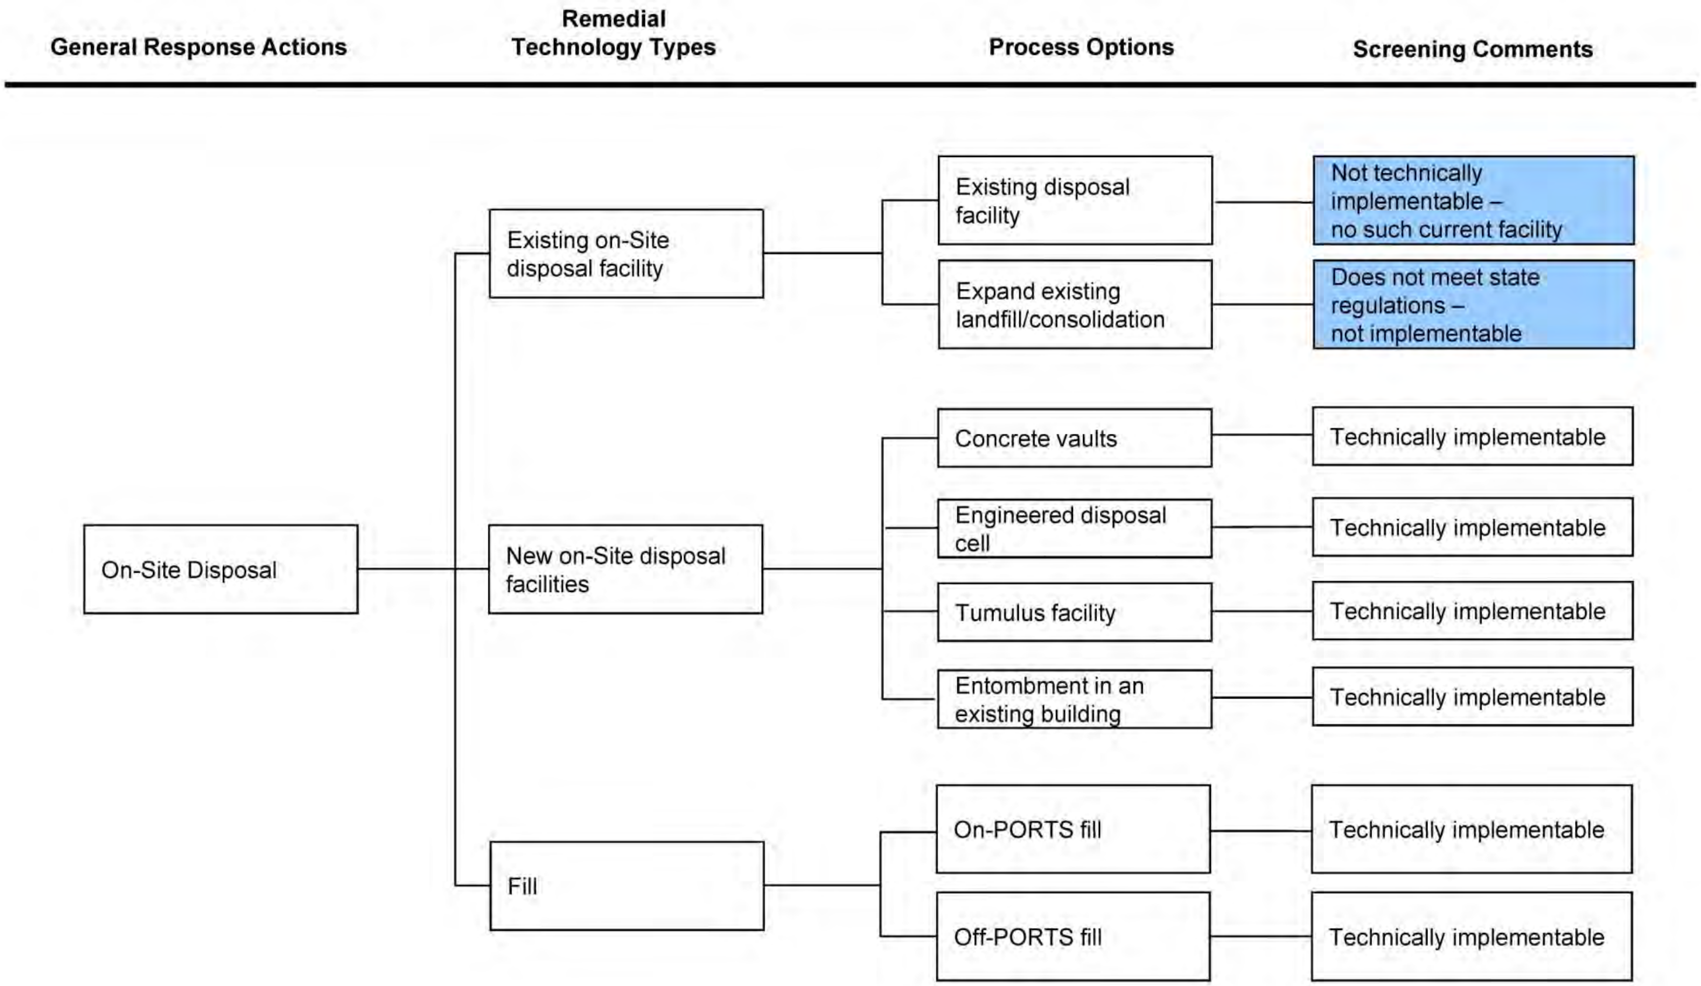

Figure 7.1. Screening of Remedial Technology Types and Process Options for PORTS (Continued)

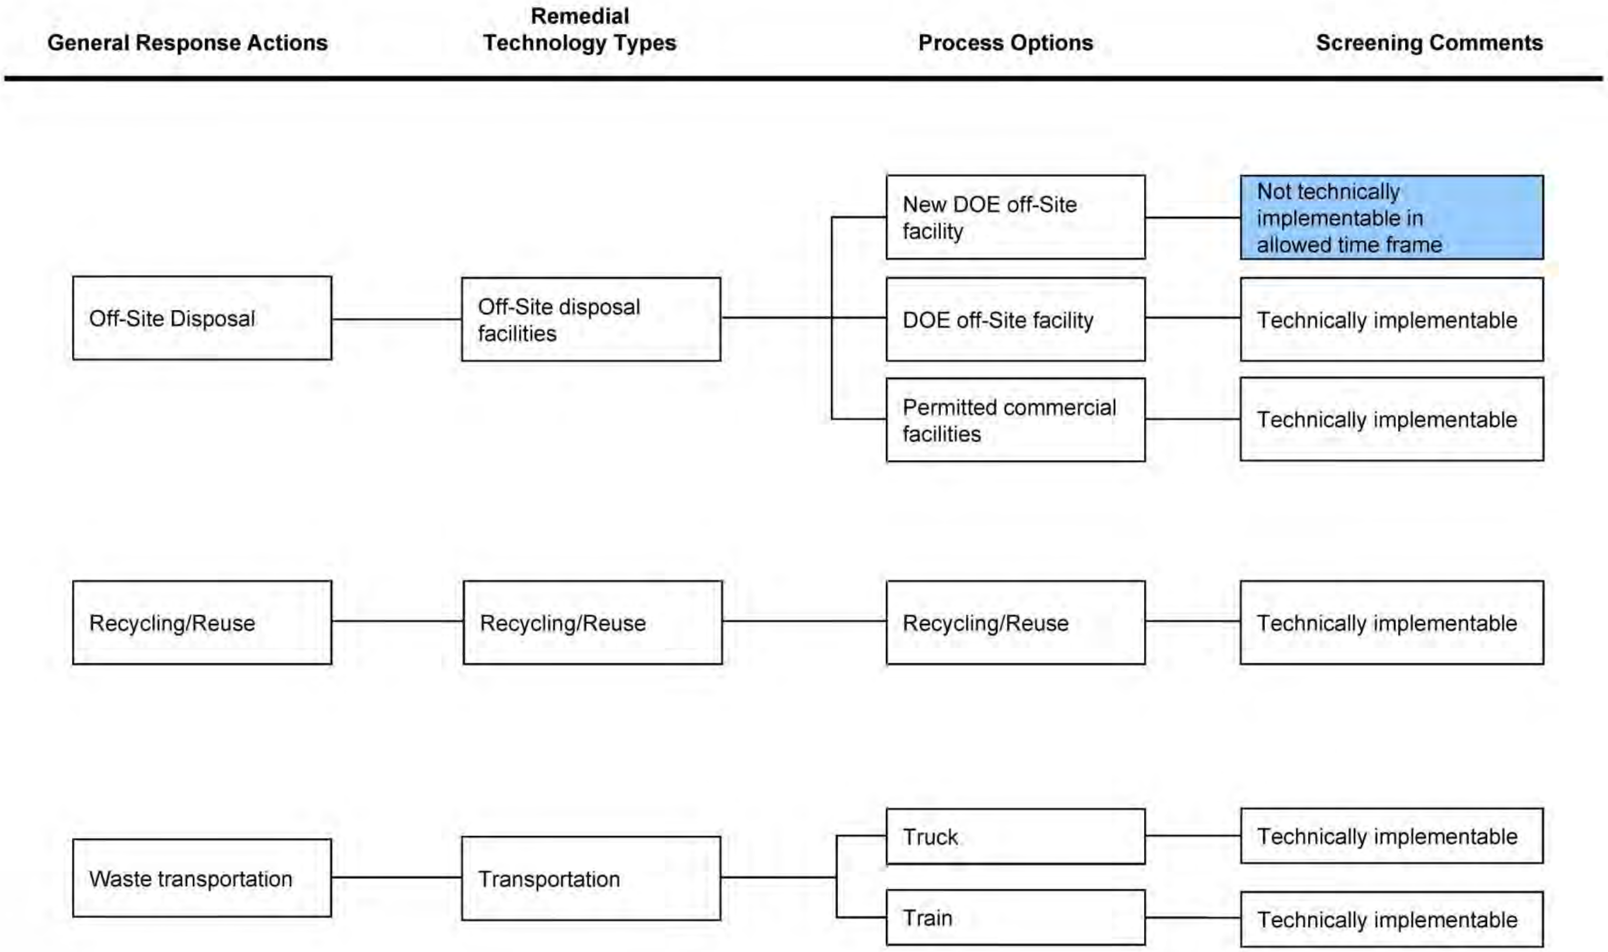

Figure 7.1. Screening of Remedial Technology Types and Process Options for PORTS (Continued)

Maintenance and Monitoring

S&M. Scheduled and special inspections of facilities and implementation of preventive or corrective measures can be used to ensure the proper operation of engineered components.

Environmental Monitoring. Sampling and analysis of environmental media before, during, and after construction of a potential on-Site waste disposal facility could be used to predict and verify the effectiveness of engineering components. Environmental monitoring could also be used to ensure human and ecological receptors are protected.

7.4.2.3 Centralized treatment

The technologies considered here are for evaluating the benefits of a centralized treatment system to address size reduction or subsidence at or near an on-Site disposal location and to support recycle and/or reuse. The technologies evaluated include physical processes, thermal processes, and decontamination. Physical processes are used to reduce the size of material, either to reduce void space or to meet other physical WAC requirements and can be done through compaction, shredding, cutting, or crushing.

Thermal processes such as melting and other decontamination processes (both physical and chemical) could be used to support future recycle and/or reuse opportunities. Construction of a new wastewater treatment plant or use of existing wastewater treatment plants to handle generated secondary wastewaters is also included.

Physical Processes

Size and Void Space Reduction. Large quantities of bulk materials, including building structural components, rebar, shielded and unshielded wire, and tanks, etc., are anticipated to be generated under any or all of the D&D decisions. There are many options for reducing the size of materials brought to a disposal or a recycling facility. Some of the larger systems (compaction, shredding, and crushing) have been evaluated in Appendix G. Compaction and shredding are useful for metals or wood waste while crushing is more often used on concrete. To implement these at a central location would require considerable design, construction, and contamination control efforts.

Macroencapsulation can also be considered to fill voids at a potential OSDC. In this case, an inert material is poured around the large pieces of equipment, providing protection against subsidence from internal void space collapsing and, in some cases, providing additional protection against contaminant leaching.

The physical processes most likely to be used include shearing with heavy equipment and manual cutting. These operations can be conducted at a centralized staging area near or on a potential OSDC or elsewhere on PORTS, as appropriate. However, to avoid double handling, a centralized size reduction operation near the disposal location is considered in this RI/FS.

Thermal Process

Melting. Thermal treatment is a unique and important treatment option to consider for PORTS D&D waste because it can reduce the toxicity and mobility of contaminants in the waste, as well as reducing the volume of waste. Any slag containing the concentrated contaminants would be packaged for on-Site or off-Site disposal, depending on the characteristics of the slag and its ability to meet the WAC. If appropriately implemented, melting technologies can decontaminate metals and allow recycle and/or reuse of the uncontaminated portion of the metals. A thermal technology processing operation could be installed in an existing or new facility at PORTS or could be undertaken at an existing off-Site facility.

Melting can create ingots for controlled recycle and/or reuse by removing contaminants through heating or slagging of the molten metal. Multiple technologies exist, including conventional technologies and state-of-the-art technologies, such as microwave or plasma heating. Conventional technologies include an electronic arc furnace and an induction furnace. Preliminary review indicates that an induction furnace is preferred for several reasons, including its ability to be cold started, improving overall operational efficiency and better control of radioactivity. Microwave and plasma heating technologies show promise, but their use is not widespread.

Decontamination
Chemical processes. Chemical decontamination processes remove surface level contamination through a chemical reaction between the contaminated object, or surface, and the decontamination solution. More aggressive decontamination solutions can penetrate deeper into the contaminated surface. The spent decontamination solution can be recycled for additional use or treated for disposal. Examples of chemical decontamination techniques include acid etching and washing with surfactants. This process option is potentially applicable to various materials, including metal and concrete materials.

Physical processes. Physical decontamination processes use force, or suction, to remove contaminated material deposits and surface contamination. Application techniques vary in aggressiveness from surface cleaning to surface removal. The contaminated residues such as dust, wipes, and blast media from removal require treatment and/or disposal. Examples of physical decontamination techniques include using needle guns, scabbling, dusting/vacuuming/wiping, and abrasive blasting. Primarily, this process option is potentially applicable to metal and concrete materials.

Secondary Wastewater Treatment
New Treatment Plant. A new wastewater treatment plant would be combined with disposal on Site to treat contaminated water generated during landfill operations. Potential sources of contaminated water include leachate, decontamination water, or contaminated storm water. Wastewater treatment would not be needed for off-Site disposal because such treatment would be the responsibility of the receiving facility. Under this process option, a new treatment plant would be built near a new disposal cell. Because the plant would be built and operated entirely on-Site in accordance with paragraph 9.a of the DFF&O, no NPDES permit would be required for discharge from the treatment facility. However, the substantive requirements of the Clean Water Act and other ARARs would be met. Wastewater would most likely be piped to a new treatment plant but could be trucked.

Existing Treatment Plant. As with a new treatment plant, this process option would be combined with disposal on Site. Under this process option, an existing wastewater treatment plant would be used to treat the contaminated landfill water from a potential disposal facility. Upgrades to the plant treatment systems or expansions for capacity may be needed. If upgrades are needed, DOE will obtain the applicable authorization for the upgrade. Which plant would be used would depend on the location of a potential OSDC. Wastewater could be piped directly or trucked to the treatment plant.

7.4.2.4 On-Site disposal

Disposal technologies include existing on-Site facilities, new on-Site facilities, and fill in support of OSDC waste placement (fill) process options. To be applicable, a facility must be able to accept the candidate waste streams consisting of LLW, RCRA waste, TSCA waste, mixed waste, and/or noncontaminated waste. Disposal locations were screened out if they could not accept some or all of these wastes or if they were not acceptable for other reasons. As shown in Figure 7.1, existing on-Site disposal facilities were screened out as they do not present a compliant and effective disposal configuration.

New On-Site Disposal Facilities

Concrete Vaults. Concrete vaults are large, reinforced-concrete, multi-celled structures constructed above or below grade. The floors, ceilings, and exterior walls of concrete vaults may be up to 2 ft thick. Concrete vaults are typically used to dispose of containerized LLW with higher activity. Once the vault cells are filled with waste containers, the void spaces are filled with sand or grout, and the vault is covered with a concrete lid. Vaults can be designed for subsequent waste removal. Although vaults are structurally stable, concrete is more permeable than clay. As a result, disposal of leachable material within a vault would require lining and capping it with a low-permeability clay or similar material for long-term containment of the waste. Low-permeability liners and caps can be used in conjunction with vaults for disposal of LLW, RCRA waste, TSCA waste, and mixed waste. Below-grade concrete vaults were not considered because of the shallow groundwater at PORTS, where such a facility would likely be sited. However, above-grade concrete vaults are technically implementable and are retained for further evaluation. To meet the required regulations, the above-grade concrete vaults would have to be combined with a liner and cover similar to that for an engineered disposal cell.

Engineered Disposal Cell. An engineered disposal cell typically consists of a multilayer liner beneath the waste, lined embankments, and a multi-layer final cover to completely encapsulate the waste. Natural materials are used extensively in cell design, and they can isolate wastes for long periods. Engineered cells are constructed to satisfy design requirements appropriate to the type of waste they would contain. The waste is placed on the bottom clay layer, which is designed to impede the percolation of any free liquids from the cell into the ground. The waste is then covered with a cap that includes an impermeable layer, a drainage layer, and a vegetative layer designed to reduce infiltration of water into the cell. The cell would include a leachate collection system to capture and remove any liquids that migrate through the cover or from the waste. An engineered disposal cell can be constructed above or below grade.

Tumulus Facility. A tumulus facility (also called entombment on a new concrete pad) consists of an at-grade concrete pad, stabilized waste, and a cover. It is typically used to contain LLW. Concrete containers of stabilized waste are stacked on the pad. The concrete pad can incorporate a leachate collection system, and an impermeable liner may be added to contain other types of waste. Once the stabilized waste containers are placed on the pad, a multi-layer cap is placed over the stacked waste to limit the infiltration of water.

Entombment in an Existing Building. Either of the two largest process buildings (X-333 and X-330) could contain the anticipated waste volume. The process equipment within the selected building would be disconnected in-place and any openings would be sealed. The infrastructure (e.g., lighting, security, fire suppression, etc.) would remain in its current state during waste placement. The concrete floor and floor drains would be sealed, and underground piping/conduits would be disconnected and sealed. The remaining waste would be placed within the selected building on the first floor for entombment. The majority of the waste would be placed in containers for easy handling and safe placement within the building. Once all waste is in place, the building infrastructure systems would be disconnected, entrances/openings would be sealed, the building would be covered with soil, and the entombed building would be placed under long-term S&M. Repairs would be performed, as needed, on the soil cover to maintain its integrity.

Fill in Support of OSDC Waste Placement (Fill)

To mitigate subsidence of waste material placed in a disposal facility, a source of fill is needed to fill in void spaces of disposed waste (EC-2). Fill is always designated as having soil-like properties and therefore is categorized as EC-1. The amount of fill required depends on the amount of waste with void spaces (EC-2) disposed and the EC-1/EC-2 ratio required by a potential OSDC. Assumptions used in determining operational requirements of a potential OSDC in this document result in a need for 2 cy of fill for every cubic yard of waste with void spaces (EC-2) disposed. Depending on the volumes of fill required, a variety of process options and borrow locations may be used. Appendix H discusses several options for obtaining large quantities of fill to provide an appropriate EC-1/EC-2 ratio. A representative process option will be identified in Section 7.4.3.4. A summary of the information presented in Appendix H follows below.

Off-PORTS fill sources. Fill is readily available from off-PORTS borrow locations. For a relatively low cost, an outside vendor can deliver fill to the location needed. A large borrow site is associated with the Pike Sanitation Landfill operation, just 5 miles from the plant.

On-PORTS fill sources. There are several potential borrow locations at PORTS. Large volumes of fill are needed, which could result in using many potential borrow locations, some of which are clean and some of which may be contaminated. A large quantity of clean soil is anticipated to be generated during the construction of a potential OSDC. This material could be processed to reduce the size of large chunks of chert, making it appropriate for use as fill. Use of this material would avoid transportation costs associated with moving fill.

There is also a large quantity of contaminated soil (RC-2, RC-3, EC-1) at PORTS. To obtain contaminated fill for use at a potential OSDC, any clean overburden or caps would be removed first and set aside, and the contaminated material underneath used as fill. This approach would minimize the amount of clean fill that would be placed in a potential OSDC. If waste requiring fill (EC-2) is encountered during the fill excavation, additional fill would be needed to meet EC-1/EC-2 ratios required for placement in the potential OSDC. For instance, if 100,000 cy of waste with void spaces (EC-2) requiring disposal were encountered, an additional 200,000 cy of fill material would be needed, over and above what is needed for the estimated D&D waste (RC-1, EC-2) volume evaluated for disposal.

7.4.2.5 Off-Site disposal

Off-Site Disposal Facilities

The evaluated off-Site disposal process options include existing LLW and mixed waste facilities, existing RCRA/TSCA facilities, and existing solid waste facilities. New disposal facilities that are appropriately permitted and licensed and become available during remedy design or implementation would also be considered.

DOE Off-Site Facility. The Nevada National Security Site (NNSS) is a federal waste disposal facility located 60 miles north of Las Vegas, Nevada. The NNSS LLW disposal facility is operated by DOE under its AEA authority. The NNSS can dispose of LLW, mixed waste, LLW/TSCA waste, classified waste, and NRC Class A/B/C waste. This disposal facility is configured to accept waste via truck but does not have direct rail access. However, combinations of rail and truck shipping can be used. Waste from PORTS has been disposed at this facility in the past.

Permitted Commercial Facilities. Energy*Solutions* has a commercial waste disposal facility in Clive, Utah. Wastes are disposed in an engineered disposal cell located in a western arid environment. The facility can treat waste for meeting LDRs and dispose of LLW and mixed waste (combinations of LLW, RCRA, and/or TSCA) that meet its WAC. The facility is configured to accept waste via truck or rail. Waste from PORTS has been disposed at this facility in the past. The Energy*Solutions* facility is operated under RCRA and LLW permits with the State of Utah.

Waste Control Specialists (WCS) is a commercial disposal facility located near Andrews, Texas. WCS is operated under RCRA and LLW permits with the State of Texas. This disposal facility can dispose of LDR-compliant hazardous waste and LLW. The facility is configured to accept waste via truck or rail.

Several RCRA- and TSCA-permitted commercial disposal facilities are available and may take portions of the PORTS waste, including:

- Waste Management, Inc. (WMI)-Emelle Division (formerly Chemical Waste Management, Inc.), Emelle, Alabama
- Rollins Environmental Services (RES), Deer Park, Texas
- United States Pollution Control, Inc. (USPCI), Clive, Utah.

All of these facilities are similar in the types of waste they receive for treatment and disposal and the services they offer. The primary difference between these facilities is the transportation distance, with the WMI-Emelle facility being the closest and the USPCI facility being the most distant. Waste disposal facilities in the western United States tend to have more favorable hydrogeologic and climatic conditions and lower local population densities than waste disposal facilities in the more humid South (such as Alabama).

The Pike Sanitation Landfill is a commercial disposal facility located in Piketon, Ohio. This facility can dispose of nonhazardous/nonradioactive solid waste, including asbestos. Waste from PORTS has been disposed at this facility in the past. There are other industrial or sanitary landfills in the area, such as the Jackson Landfill, with very similar operational requirements that could also be considered.

7.4.2.6 Recycling and/or reuse

DOE is committed to the recycle and/or reuse of materials from PORTS in compliance with ARARs. Recycle and/or reuse removes volumes of waste from the waste streams that need to be disposed. Recycle and/or reuse of material would decrease the waste volume to be disposed, and therefore either decrease the size of the disposal cell for the on-Site option or decrease the volume of material to be sent off Site as waste. Typically, recycled clean scrap or metal is reused to create new metal items. Crushed concrete could be used in a potential OSDC as fill material around objects, for wet weather access roads, or as fill elsewhere on PORTS. Crushing concrete for use as fill in a potential OSDC would decrease the volume of waste to be placed, thereby decreasing the volume of clean fill needed to maintain the desired EC-1/EC-2 ratio. Recycling and/or reuse can be implemented on Site (crushing and reusing concrete), materials could be treated on Site (e.g., metal melted) and reused off Site, or materials could be treated and reused off Site. Preparation for individual waste stream recycling and/or reuse is addressed in the Process Buildings and Complex Facilities D&D Evaluation Project. Consideration of a centralized waste treatment system to prepare waste streams from multiple projects is included in this project.

7.4.2.7 Waste transportation

Transportation vehicles are used in conjunction with packaging (evaluated in the Process Buildings and Complex Facilities D&D Evaluation RI/FS) for relocation of waste to treatment or disposal facilities. Some transportation vehicles can be equipped to provide containment without additional packaging of the waste (such as gondolas and railcars). These technologies and the associated process options are considered to be technically implementable and would be used in conjunction with waste disposal process options.

Transportation

Truck. Truck transport is applicable to both local and long-distance waste transport. Trucks can transport bulk or containerized wastes. Waste being shipped off Site by rail has to be transferred from trucks to railcars at a truck-to-rail transfer facility. All off-Site disposal facilities are configured to receive waste directly via truck. A number of small containers such as lab packs, B-25 boxes, drums, and overpacks are designed to contain various waste forms (e.g., solid, granular, etc.) and types (e.g., LLW, RCRA, etc.). Small containers would be applicable to certain specific candidate waste streams. Small containers are typically disposed with the waste rather than emptied and reused.

Large containers include roll-off bins, Sea-Land containers, intermodal containers, and other containers with various weight and volume capacities, loading capabilities (top-, side-, or end-loaded), and handling characteristics. Large containers can be moved by forklift or crane and also can be winched onto a truck bed. Some truck-mounted containers can be unloaded directly by dumping from the truck, while other containers must be removed and unloaded with additional equipment. Large containers can usually be decontaminated and reused. Dedicated containers can be reused for similar waste streams with only external decontamination.

Train. Rail transport would be viable for long-distance waste transport. Rail transportation most often includes the use of gondola containers or intermodal/Sea-Land containers. A variety of waste forms and types can be loaded into the containers. Railcars can be loaded from trucks at a truck-to-rail transfer facility. PORTS has extensive railroad infrastructure. One-third of the approximately 17 miles of on-PORTS railroad infrastructure is in service and is being periodically used. The remaining two-thirds of the infrastructure is out of service and would need to be upgraded. The existing on-PORTS railroad infrastructure is connected to an active off-PORTS rail line near the northwest corner of PORTS. A small portion of the on-PORTS rail infrastructure is currently being used to load flatbed railcars with intermodal containers of radioactively contaminated waste and scrap metal for off-PORTS shipment and disposal (TPMC 2007). The Energy*Solutions* and WCS disposal facilities are configured to accept waste via rail.

7.4.3 Evaluation and Selection of Representative Process Options

EPA guidance (EPA 1988) and the DFF&O (Section 7.2 of the SOW for the RI/FS) discuss evaluating the effectiveness, implementability, and cost of each process option within the same technology type that passed the initial screening step to identify representative process options. Based on this evaluation, the process option that best satisfies the criteria of effectiveness, implementability, and cost for each technology group is identified as the representative process option. The representative process options identified from this evaluation are indicated by shading in Table 7.1. These process options "represent" other process options only in this FS evaluation. Future evaluation may result in the use of other, comparable process options, including options that are not shaded in this table. Because a process option is not shaded in this table, it does not mean that it could not be used.

7.4.3.1 No Action

Effectiveness. This process option would not address long-term waste disposal concerns. Allowing waste to accumulate at PORTS would not be protective of human health or the environment.

Implementability. The no-action option is easily implementable.

Cost. No cost is associated with the no-action option.

Table 7.1. Evaluation and Selection of Representative Process Options for PORTS

General Response Action	Technology Type	Process Option	Effectiveness	Implementability	Cost	Status
No Action	None	No action	Response would not address waste storage/disposal concerns.	No implementation required.	None	Identified as the representative process option to provide baseline.
Institutional Controls	Access and use restrictions	Physical barriers/security	Effective for preventing access to waste as long as institutional controls are maintained. Not effective for controlling migration of contaminants off PORTS.	Readily implemented with available technology.	Low	Identified as representative process option.
		Covenants and deed restrictions	Effective for preventing human activities that may impact buried waste, as long as institutional controls are maintained. Not effective for controlling off-PORTS contaminant migration.	Readily implemented with no adverse impacts to workers or the public.	Low	Identified as representative process option.
	Maintenance and monitoring	Surveillance and maintenance	Effective for determining the performance and continued integrity of engineered systems and maintaining systems to ensure waste containment.	Readily implemented with personnel conducting inspections and maintenance.	Low	Identified as representative process option.
		Environmental monitoring	Effective for detecting contaminant migration because of changes in conditions, waste forms, and engineered features.	Equipment and personnel are readily available.	Low	Identified as representative process option.
Centralized Treatment	Physical processes	Size and void reduction	Wide variety of effectiveness. Large equipment such as compactors, shredders, and concrete crushers only effective on portion of waste. Heavy equipment and manual cutting less specific and may be more effective.	Large equipment such as compactors, shredders, and concrete crushers difficult to implement (major design, construction, contamination control needed). Heavy equipment and manual cutting easy to implement. Macroencapsulation very slow to implement.	Low to high	Identified as the representative process option. Heavy equipment and cutting used to represent a centralized physical treatment process due to wider application and fewer implementability issues.
	Thermal processes	Melting	Effective at reducing waste volume and decontamination. Only useful for a portion of the waste streams.	Even more complex than other volume/size reduction process options.	Very high	Not identified as the representative process option at this time. May be reconsidered in the future.

Table 7.1. Evaluation and Selection of Representative Process Options for PORTS (Continued)

General Response Action	Technology Type	Process Option	Effectiveness	Implementability	Cost	Status
Centralized Treatment (continued)	Decontamination	Chemical processes	Effective for removing organic, inorganic, PCB, and radiological contamination, primarily from metal and concrete.	May require design and construction of reaction vessels. Could generate large quantities of secondary waste requiring treatment.	Moderate to high	Identified as the representative process option.
		Physical processes	Effective at removing loosely bound contamination from concrete/metal surfaces. More aggressive techniques also effective at removing uranium material deposits.	Experienced personnel and equipment are available. Uranium deposit removal would be labor intensive.	Moderate	Identified as the representative process option.
	Secondary waste water treatment	New treatment plant	Effective at removing contamination from contact water and leachate from a potential OSDC.	Cap and design as needed. Standard technologies would be used and are available.	Moderate	Identified as the representative process option.
		Existing treatment plant	Effective at removing contamination from contact water and leachate from a potential OSDC.	Would need to retrofit existing small, specialized plants. More difficult to implement.	Moderate	Not identified as the representative process option due to effort in retrofitting a plant.
On-Site Disposal	New on-Site disposal facilities	Concrete vaults	Effective for short half-life radionuclides in containers. Concrete subject to cracking. Additional liners required to control contaminant migration. Long-term maintenance required.	Straightforward to implement. Limited flexibility in accepting varying waste forms or modifying design capacity. Large land area needed. Significant administrative requirements for siting and approval.	Moderate	Not identified as the representative process option. Less protective than engineered disposal cell.
		Engineered disposal cell	Effective for isolating wastes from the environment. Natural materials, such as clay, in liners and caps increase longevity of the facility. Long-term maintenance required.	Straightforward to implement. Most flexible for greater or lesser eventual volumes. Construction and operations relatively easy. Significant administrative requirements for siting and approval.	Moderate	Identified as the representative process option.
		Tumulus facility (entombment on a new concrete pad)	Effective for isolating short-lived radionuclides in containers. Concrete subject to cracking. Additional liners required to control contaminant migration. Long-term maintenance required.	Technically implementable. Modular construction allows expansion. Operations moderately complex. Large land area needed.	Moderate	Not identified as the representative process option. Less protective than engineered disposal cell.

Table 7.1. Evaluation and Selection of Representative Process Options for PORTS (Continued)

General Response Action	Technology Type	Process Option	Effectiveness	Implementability	Cost	Status
On-Site Disposal (continued)	New on-Site disposal facilities (continued)	Entombment in existing building	Not expected to be effective for long-term disposal. No measures in place to control contaminant migration. Floor would fail, allowing contaminant migration.	Extremely difficult to implement. Small footprint requires extra height. Difficult to place waste.	Moderate	Not identified as the representative process option because of concerns with contaminant migration and implementation difficulties.
	Fill	Off-PORTS fill	Effective in procuring sufficient fill to meet large demands.	Easiest process option. Only need to direct truck drivers to location fill is needed.	Low	Not identified as the representative process option.
		On-PORTS fill	Should provide sufficient fill effectively.	More effort needed to either discover and mine new borrow locations, to process soil from potential OSDC construction, or to excavate contaminated fill.	Low/ Moderate (low if clean, moderate if contaminated)	Identified as the representative process option.
Off-Site Disposal	Off-Site disposal	DOE off-Site facility	Permitted facility in an arid environment (near Las Vegas, Nevada), well away from population centers, and effective at isolating wastes. Waste is removed from PORTS. No long-term potential PORTS exposure concerns or maintenance requirements.	Readily implementable. PORTS is currently shipping waste there. Accepts LLW via truck. Administrative concerns regarding interstate waste shipment.	Low to Moderate	NNSS identified as representative off-Site LLW and MLLW disposal option.
		Permitted commercial facilities	Permitted facilities, some in an arid environment, well away from population centers, and effective at isolating wastes. Source term is removed from PORTS. No long-term potential PORTS exposure concerns or maintenance requirements.	Readily implementable. Accepts wide variety of wastes, including LLW, mixed, and industrial.	Low to high	Identified as representative process option. Energy*Solutions* is used for purposes of alternative analysis for LLW, MLLW and Pike Sanitation Landfill is similarly used for construction debris.
Recycle and/or Reuse	Recycle and/or reuse	Recycle and/or reuse	Effective at reducing volume requiring disposal.	Readily implementable. Already recycling/reusing certain materials from PORTS.	Varies. Generally low	Identified as the representative process option.

Table 7.1. Evaluation and Selection of Representative Process Options for PORTS (Continued)

General Response Action	Technology Type	Process Option	Effectiveness	Implementability	Cost	Status
Waste Transportation	Transportation	Truck	Effective for safely transporting wastes over long distances. Wastes can be shipped portal-to-portal without additional waste handling.	Readily available and commonly used for waste transportation. Greatest flexibility in travel routes and scheduling.	Moderate	Identified as the representative process option for transport of construction debris and LLW off PORTS.
		Train	Effective for transporting wastes over long distances. Because some waste would be initially loaded on trucks at the point of origin, rail transport may require double handling of certain waste at the truck-to-rail transfer facility at PORTS and at the disposal facility.	Readily available and commonly used for waste transportation. Less flexibility in travel routes and scheduling. Fewer disposal facilities configured to receive rail shipments.	Moderate	Identified as the representative process option for transport of LLW and mixed waste off PORTS.

Note:
Representative process options are shaded.

DOE = U.S. Department of Energy
LLW = low-level (radioactive) waste
MLLW = mixed LLW
NNSS = Nevada National Security Site
OSDC = on-Site disposal cell
PCB = polychlorinated biphenyl
PORTS = Portsmouth Gaseous Diffusion Plant

7.4.3.2 Institutional controls

Access and land-use restrictions, as well as maintenance and monitoring, are institutional controls that could reduce the potential for exposure to waste placed in an on-Site disposal facility. These technologies and the associated process options are considered to be technically implementable and would be used in conjunction with on-Site waste disposal process options.

Access and Use Restrictions—Physical Barriers, Security, Covenants, and Deed Restrictions
Effectiveness. Physical barriers (such as fences) and security forces would be used around any construction operations or any long-term on-Site disposal facilities. These physical controls discourage visitors and unauthorized personnel from coming in contact with contamination during construction activities or from damaging a closed on-Site landfill. Administrative controls such as covenants and deed restrictions prevent inadvertent reuse of areas of the Site with long-term unacceptable risks to future users. These covenants or restrictions would prevent the installation of drinking water wells and construction activities on, or near, any on-Site disposal facility.

Implementability. All access and use restrictions are readily implementable. The government has used these tools at all government facilities, and use of these process options represents a continuation of existing conditions.

Cost. All of the process options associated with access and use restrictions are fairly low cost. Long-term costs are associated with certain elements such as physical barriers and security because of the need to have these process options in place as long as any unacceptable risk remains.

Identification of Representative Process Options. All access and use restrictions are identified as representative process options. As opposed to one selected over another, depending on the classified nature of an on-Site disposal facility, any or all of the institutional control process options could be used together to provide the level of protection needed.

Maintenance and Monitoring—S&M and Environmental Monitoring
Effectiveness. Surveillance can effectively evaluate the integrity of engineered systems, and maintenance can ensure integrity for the duration of active institutional controls. Environmental monitoring is effective for detecting contaminant migration and assessing the reliability of containment and engineering systems. Environmental monitoring can include monitoring of leachate, surface water, or groundwater. Monitoring itself does not protect the environment because it cannot control the spread of contamination. However, frequent and early detection of problems does allow effective engineered solutions to be put in place to control unexpected releases, thereby contributing to protection of the environment. Combining S&M and monitoring can protect the environment.

Implementability. S&M and environmental monitoring are readily implemented with current technologies. New monitoring locations would need to be placed for any new on-Site disposal facility. Minimal administrative complexities are envisioned for monitoring well installation or identification of surface water monitoring locations.

Cost. All of the process options associated with maintenance and monitoring are fairly low cost. There are long-term costs because of the need to have these process options in place as long as any unacceptable risk remains.

Identification of Representative Process Options for Institutional Controls. The S&M and environmental monitoring process options are identified as representative process options to be combined with on-Site disposal or on-Site treatment options.

7.4.3.3 Centralized treatment

Treatment is under consideration as a precursor to recycling and/or reuse or to treat waste generated by operating a potential OSDC. This GRA includes physical processes, a thermal treatment process option, decontamination, and secondary wastewater treatment process options. Several of the physical and thermal process options are all evaluated in more detail in Appendix G.

Physical Size Reduction

Effectiveness. Volume reduction technologies (such as cutting, compaction, shredding, shearing, and dismantlement) could be effectively used to reduce waste volumes and meet packaging, transportation, or disposal requirements. Compaction has been used in Oak Ridge. It is an effective method if a sufficiently sized compactor is used. Initial size reduction through cutting or shearing of the waste is typically needed to meet compactor feed requirements. Compaction is used routinely and effectively on other types of waste. It is not used on solid items such as the larger block valves and the heavier steel plate items. Shredding has not been used at full scale at a GDP, but it should be effective at reducing the volume and void spaces of process equipment and other waste. It also requires cutting or shearing first, as do the other centralized treatment systems. Shredding reduces large metal components to smaller shards of metal that can be easily mixed with other waste, compacted, and placed in a landfill. Shredding can be used on other waste streams such as wood to render them smaller, requiring less fill or cover in a disposal cell. The volume reduction should be similar between the shredder and the compactor. Shredding and compaction bring significant industrial safety concerns associated with their large-scale implementation, but there are numerous engineering and administrative controls that can be put in place to minimize risks to workers. Crushing, either at the area of generation with heavy equipment or at a central concrete crushing facility, can effectively size reduce concrete enough to allow it to be reused, depending on its level of contamination. The productivity of a centralized concrete crushing system would be greater than the productivity of heavy equipment for large volumes of material. Size reduction by shearers and through manual cutting can be very effective as they can be used on almost any type of waste.

Macroencapsulation of process equipment using reinforced concrete would reduce the mobility of contaminants in the equipment as well as prevent subsidence that could result from degradation of the external shell of the equipment. Macroencapsulation is an effective means to handle void spaces in large equipment. It also has lower worker exposure potential than the process options that change the nature of the process equipment.

Implementability. Physical size reduction techniques are readily implementable using standard industrial equipment and techniques. However, in most cases, the waste needs to be size reduced first to fit into the hopper of the equipment. Then, after size reduction, the equipment pieces need to be moved again to the centralized treatment location. The equipment, both compactors and shredders, needs to be equipped with high-efficiency particulate air filters to control air emissions. A centralized concrete crusher would be easier to implement than compaction and shredding but it is much easier to use heavy equipment for small scale use. Shearing and cutting are easy to implement. The equipment is readily available and can be sized to meet any production need. To effectively implement macroencapsulation, forms are needed to ensure the concrete completely surrounds the piece of equipment. This process option is labor intensive. The equipment must be placed carefully, and the concrete must be poured slowly and evenly around the equipment. All options are considered implementable.

Cost. Shredding and compaction are both expensive endeavors. The construction and operation costs of either process option are comparable and quite high. The equipment is not readily available and would have to be designed and constructed for use on radioactive waste streams. There would also be significant power demands. Because of the limitations of each option, significant quantities of waste could not be processed, meaning the benefits of either process option would be applicable to only a fraction of the waste volume generated. Total costs for this process option are considered to be high compared to other means of reducing volume or limiting void space. Costs are lower for concrete crushing and macroencapsulation because of greater equipment availability and routine operation. The least expensive would be shearing and cutting.

Thermal Process
Effectiveness. Thermal process options such as melting could be effective at reducing toxicity and mobility of contaminants associated with D&D-generated metals. It is excellent for eliminating void space and is more effective than shredding and compacting as all void spaces are removed. Some of the benefits of the melting process include encapsulation of residual contaminants in slag and declassification of classified components and materials. As with compaction and shredding, melting is inherently a dangerous process option, but risks to workers can be controlled with engineering and administrative controls.

Implementability. Implementation of thermal technologies would require substantially more effort than the other treatment process options. A thermal treatment unit could be installed within an existing or new facility at PORTS. A thermal treatment unit would include a decontamination/preparation area for the feed material, a furnace, a staging area for the ingots and slag, and air pollution control equipment. As with the physical size reduction process options, melters require some additional segmentation of subassemblies before placement of the metal. Melting has not been used at full scale on process equipment, so there are numerous uncertainties surrounding its implementation. Addressing these uncertainties in combination with the time required to design, build, and test a new treatment system adds to the challenges. Melting would be considered readily implementable for smaller quantity, relatively homogeneous waste streams but progressively more difficult to implement as the size of the waste stream and heterogeneity increases.

Cost. Thermal treatment is likely to be more expensive than the other physical processes discussed above. The equipment is not readily available and would have to be designed and constructed for use on radioactive waste streams. The high power and fuel demand of this process option increases operation costs. Total costs for this process option are considered to be very high compared to other means of reducing volume or limiting void space. A large volume of estimated waste streams could not be processed, meaning the benefits of this process option would be applicable to only a fraction of the waste volume generated.

Decontamination – Chemical Processes and Physical Processes
Effectiveness. Chemical processes such as acid etching and washing with surfactants have been demonstrated to be effective in removing organic, inorganic, PCB, and radiological contamination, primarily from metal and concrete surfaces. Physical processes such as needle guns, dusting/vacuuming/wiping, and abrasive blasting are effective at removing loose bound contaminants, primarily from metal and concrete surfaces. Physical processes are also effective on uranium deposits contained in process equipment and piping. These techniques were used at PORTS during operation of the GDP. For the appropriate use, each process option is considered to be effective. Centralized chemical processing may be effective at decontamination of volumetrically contaminated materials such as the nickel barrier

materials. Treatability studies may be required to provide proof-of-process data and engineering information important to full-scale design.

Implementability. In general, chemical processes are more difficult to implement than physical processes. Depending on the particular chemical process used, an immersion or reaction vessel may be needed to perform the chemical reaction. Chemical processes can create large quantities of secondary waste (decontamination solution), which in most cases requires treatment prior to disposal. Physical processes are relatively easy to implement with conventional cleaning supplies and equipment. Depending on the amount of decontamination required, implementing physical processes can be labor intensive. Secondarily generated waste (e.g., wipes, paint chips, filters, grit) can usually be disposed of without treatment. It should be noted that the application of physical and chemical decontamination processes would be material-specific and heavily dependent on the nature of contamination.

Cost. The costs to use chemical processes are considered to be medium to high, and they include costs for the decontamination solution, construction of the decontamination unit (reaction vessel), operation of the process, and treatment and disposal of the secondary waste. The costs to use physical processes are considered to be medium and include the costs for materials (e.g., vacuum filters), operation of the process (vacuuming), and disposal of the secondary waste (spent vacuum filters).

Secondary Wastewater Treatment
Effectiveness. Treatment of contaminated disposal facility operations water, such as leachate and runoff during construction and operation from a new potential OSDC, would be effective. Organic compounds including PCBs along with metals and radionuclides are the contaminants that would likely require treatment. Numerous technologies that can remove these contaminants from water are available, but they would have to be constructed on Site. The current on-PORTS treatment facilities are specialized groundwater treatment plants for TCE or sanitary wastewater treatment plants. These plants do not have the appropriate technologies or capacities to treat the wastewater streams from a new potential OSDC without significant upgrades.

Implementability. The only treatment plant within a reasonable distance from a potential OSDC location (Study Area D) is a sanitary wastewater treatment plant. If upgrades are needed, DOE will obtain the applicable authorization for the upgrade. Trucking contact water adds substantial logistical considerations to operating a disposal facility. Piping with facilitated pumping would be the easiest method. Piping is most cost-effective when the treatment plant is nearby. However, the effort involved in converting the nearest treatment plant to one that would meet the needs of any new disposal operation would be as great, if not greater, than constructing a new treatment facility. A new treatment facility could be built at the most convenient and cost-effective location.

Cost. The costs for upgrading existing treatment plants or constructing new plants are comparable. With regard to modifying the small, specialized treatment plants at PORTS, new construction may be the most cost-effective. In either case, the costs are considered to be moderate.

Identification of Representative Process Options for Treatment. A new centralized wastewater treatment plant is identified as the representative process option for treating contaminated leachate, decontamination waters, and contaminated storm water from a new potential OSDC. Although an existing plant could be upgraded, the extent of the system upgrades and the long distance of new piping runs might remove any cost benefit that otherwise might be expected.

The D&D of PORTS is anticipated to generate approximately 1.47 million cy of materials and waste from the demolition of the GDP. Physical processes conducted in a centralized facility to reduce size and void spaces (primarily shearing with heavy equipment and manual cutting), in support of recycling and/or reuse and to meet disposal facility WAC, have been identified as the representative process options. Due to the magnitude of the projects and the varying types of characteristics of the waste materials and contaminants, all treatment process options including upgrading an existing wastewater treatment plant may be considered in the future for possible application, as required.

7.4.3.4 On-Site disposal

New On-Site Disposal Facilities

Effectiveness. Vaults and tumulus facilities are constructed of concrete, which is less impervious than clay and may crack or otherwise degrade over time when compared to an engineered disposal cell. Multilayer liners can be added to vaults or tumulus facilities to increase their effectiveness in isolating waste from the environment. There are weight limitations on the bearing capacities of concrete structures and, consequently, limitations on the height and amount of waste that can be placed in vaults or tumulus facilities. Long-term maintenance needs could be significant.

Engineered disposal cells use natural materials that are more effective than concrete at long-term isolation of waste constituents and that have more durability than concrete. Most of the anticipated PORTS waste is expected to contain long-lived radionuclides or chemicals that do not degrade or lose toxicity (such as heavy metals). Engineered disposal cells are more effective than vaults or tumulus facilities without liners at containing contaminants long term. Engineered disposal cells are as effective as concrete facilities with liners.

Either of the two largest process buildings (X-330 or X-333) could be used to entomb the anticipated waste volume from PORTS. However, the buildings were not designed for this use. The building floors and drains could be sealed prior to waste placement, but there are no engineering mechanisms to prevent contaminant migration from the entombed waste. The concrete floor likely would fail eventually because of the weight placed on top of it, allowing contaminants to migrate into underlying groundwater.

Implementability. Construction of concrete vaults, an engineered disposal cell, a tumulus facility, or use of an existing building for entombment is technically implementable using standard construction techniques and readily available materials. For similar waste capacities, vault or tumulus construction is much more time consuming and labor and material intensive than engineered cell construction. The concrete-based facilities require repetitive installation of formwork, concrete placement, and stripping of the form work. Curing time must be allowed for the concrete. Construction of an engineered disposal facility uses standard earthmoving equipment to place the natural materials that form the containment layers. This construction could proceed relatively rapidly. Installation of leachate collection systems would be similar for concrete vaults, tumulus facilities, or an engineered disposal facility. Use of man-made liners and cover materials in an engineered disposal cell would be readily implementable.

Waste placement operations would be easier at an engineered disposal facility than at a concrete vault or tumulus facility. Earthmoving equipment could be used for placement of bulk soil-like waste in an engineered cell. Small containers and other solid waste forms could be intermixed with bulk waste to minimize void spaces. Limitations on vault or tumulus container size and height would make waste placement more time consuming and not as efficient.

An engineered disposal cell can be constructed in stages and readily accommodate changing waste forms and volumes. Tumulus facilities can be modular, and extra pads and containers can be added relatively easily. A vault facility design is much less flexible in accommodating changing conditions. The land area required for a vault or tumulus facility could be several times that required for an engineered disposal facility because of height limitations, space required between adjacent tumulus pads or concrete vaults, and the additional volume required by the concrete walls, containers, and flowable fill.

Use of the process buildings for entombment of anticipated waste is implementable, although the selected building would require significant modifications. Waste could be placed on the first floor only because of the load-bearing limitations on the second floor. The majority of the waste would require containerization for ease of handling and safe placement within the building structure. Waste placement in the buildings would be time consuming because the equipment used to move containers would have to maneuver around the existing building columns.

Cost. Compared to treatment process options, these on-Site disposal process options are moderately expensive. To bring vaults, tumuli, and entombment into compliance with disposal regulations associated with leachate and liner systems, however, would increase the costs of these options to greater than the cost for an engineered disposal cell. Operations would also be more expensive.

Fill in Support of Potential OSDC Waste Placement (Fill)

Effectiveness. Both on-PORTS and off-PORTS borrow locations are considered effective fill options. There are enough off-PORTS sources of fill to allow the project to buy the volume of fill necessary to support waste disposal at a potential OSDC. If the excess soil from the construction of a potential OSDC is considered, there is enough clean fill on PORTS, although the construction soil may have to be processed to provide the consistency needed to support the operation. Use of excavated contaminated fill materials (RC-2, RC-3) should provide sufficient volume, and it can easily be supplemented with clean fill, as appropriate. More information about the effectiveness, implementability, and cost of these options can be found in Appendix H.

Implementability. Buying off-PORTS fill would be the easiest option to implement. The fill could be delivered where and when it was needed. Developing clean fill on PORTS also would be reasonably easy, but more effort would have to be put into finding, removing, or processing the soil to provide the quality needed for fill.

Excavating contaminated fill (RC-2, RC-3, EC-1 and EC-2) would pose greater challenges. First, additional radiological and contaminant migration controls would be needed that would not be required during the excavation of clean fill. Secondly, if waste with void spaces (EC-2) were encountered, additional fill would be needed. The excavation of waste (RC-2, RC-3) would require detailed anomaly detection to ensure only waste that would meet the WAC would be sent to a potential OSDC. Third, deep excavations might be needed to access sufficient volume. These open excavations would collect groundwater or rain water that would likely require treatment. Fourth, additional effort would be required to obtain regulatory approval for excavation and placement of contaminated fill. Finally, restoration of the excavations might be challenging to provide the correct drainage.

Cost. The cost to purchase or make on- or off-PORTS clean fill would be relatively inexpensive. There would be considerable volumes of excess soil remaining after construction of a potential OSDC that could be processed for fill, resulting in almost no transportation costs. However, the cost for excavating contaminated fill (RC-2, RC-3, EC-1 and EC-2) would be higher due to the fact that the work would be in a contamination zone. Some of the excavated material might not meet the WAC of a potential OSDC and might need to be treated or shipped off Site for disposal, all adding to the costs.

Identification of Representative Process Option for On-Site Disposal. The engineered disposal cell is being identified as the only process option for new on-Site disposal facilities because of equal or better long-term effectiveness, easier implementability, and equal or lower costs. After evaluation, entombment is not considered to be effective and is extremely difficult to implement. A new cell would have the greatest design flexibility, and its significant use of natural materials enhances its long-term durability and, consequently, its ability to reduce the potential for contaminant migration over that of vaults and tumuli. Use of on-PORTS fill at a potential OSDC is being identified as the representative process option for fill (RC-2, RC-3, EC-1). The final determination of the actual source of fill to support waste placement in a potential OSDC is not being made in this RI/FS.

7.4.3.5 Off-Site disposal

DOE Off-Site Facility

Effectiveness. NNSS is effective at isolating wastes from the environment and has the added benefit of being located in arid or semi-arid environments away from population centers. Because the anticipated wastes would be removed from PORTS and shipped to an off-Site facility, there would be no PORTS maintenance requirements or long-term exposure concerns for PORTS receptors. NNSS can dispose of LLW, mixed waste, LLW/TSCA waste, classified waste, and NRC Class A/B/C waste. NNSS is the only facility that can accept classified waste and all classes of LLW.

Implementability. PORTS wastes from various projects have been shipped to NNSS facilities in the past. The long-term availability of any existing facility is uncertain because of the inherently uncertain nature of commercial enterprises. However, other facilities with similar capabilities could be developed over the long term.

Cost. The cost can vary depending on the waste stream. It is considered moderate to high.

Permitted Commercial Facilities

Effectiveness. All of the existing RCRA/TSCA facilities under consideration are engineered to be effective at isolating wastes from the environment. The RES and USPCI facilities receive waste by truck only. Although these facilities in the western United States (RES, USPCI) have the benefit of being located in a drier climate than the WMI-Emelle facility, transportation distances from PORTS to the western facilities are much greater. Energy*Solutions* is licensed to dispose of mixed waste (LLW/RCRA). The other permitted and available off-Site facility is the Pike Sanitation Landfill. Waste that meets its WAC (uncontaminated solid or construction and demolition debris) can be effectively isolated from the surrounding environment.

Implementability. All facilities can readily accept waste that meets their respective WAC. Although shipment to all facilities is readily implementable, there are U.S. Department of Transportation (DOT) requirements for interstate shipment of wastes (such as placarding, routes, and packaging) that must be met.

Cost. The permitted off-Site commercial facilities vary in cost from low for Pike Sanitation Landfill to high for the facilities that can accept mixed RCRA/TSCA/LLW facilities.

Identification of Representative Process Options for Off-Site Disposal. Disposal in an off-Site government-owned or an appropriate licensed commercial facility is identified as the representative process option for off-Site disposal for remedial alternative development. NNSS is adopted in this RI/FS as the representative government disposal facility for purposes of alternative analysis. The Energy*Solutions* facility and Pike Sanitation Landfill are adopted as the representative facilities for purposes of alternative evaluation for off-Site waste disposal at a commercial landfill for mixed and solid waste, respectively. Other existing commercial facilities such as the WCS facility in Andrews, Texas, or new off-Site, appropriately licensed or permitted facilities, which emerge following issuance of this RI/FS, may be used.

7.4.3.6 Recycling and/or reuse

Effectiveness. DOE is committed to recycling and/or reuse. For some waste streams, decontamination and recycling and/or reuse is very effective whereas for others it is not feasible. DOE would make determinations for recycling and/or reuse on a waste stream basis.

Implementability. Recycling and/or reuse has proven to be a valuable and implementable component of similar D&D projects conducted at other DOE and commercial locations. The ease of implementation of recycle and/or reuse is directly related to many factors, including the nature of the material, contaminant properties, and governing requirements. Implementation of recycle and/or reuse is considered a component of all remedial action alternatives.

Cost. The cost of recycle and/or reuse would be determined on a waste stream basis.

Identification of Representative Process Options for Recycling and/or Reuse. Recycling and/or reuse is identified for alternative development. Recycling and/or reuse decisions would be determined by DOE on an individual waste stream basis.

7.4.3.7 Waste transportation

Effectiveness. Trucks and trains are effective and reliable modes of off-PORTS waste transportation. Rail transport normally requires truck transportation of waste from the generator area to a rail transfer facility at PORTS, as well as waste loading equipment. Thus, it is assumed that the use of trains could involve an additional waste handling step incurred at the on-PORTS transfer facility. Bulk waste could be effectively contained in enclosed truck beds or railcars. The representative LLW or mixed waste disposal facilities accept both truck and rail waste shipments.

Implementability. Both process options are readily implementable. If rail transportation were used, the existing truck-to-rail transfer facilities at PORTS would require expansion. The rail infrastructure is assumed to require upgrading and possible reconfiguration or expansion to accommodate greater waste volumes and frequencies of shipments. Waste could be transported by truck from the point of generation to an off-Site disposal facility, whereas the rail option could require additional waste handling steps at a truck-to-rail transfer facility and at the disposal facility. Use of large-container packaging would simplify the handling process.

Cost. Although the disposal facilities charge less for bulk waste delivered by truck, charges for containerized waste are the same for truck and rail. On average, the costs for both transportation methods are considered to be moderate. A truck trip to Pike Sanitation Landfill would be very inexpensive. A truck carrying an oversized piece of process equipment, properly packaged, to a location in the west would be a very expensive trip. Both truck and rail transport can be cost-effective, but for different waste streams and disposal locations.

Identification of Representative Process Options for Waste Transportation. Truck and rail transport are identified as representative process options. Each would be used, depending on the disposal option under consideration.

7.5 WAC FOR REPRESENTATIVE WASTE DISPOSAL FACILITIES

In accordance with requirements outlined in the DFF&O, draft WAC are to be included in the FS if a considered alternative includes a newly constructed waste disposal facility at PORTS. WAC for both on-Site and off-Site disposal facilities that are representative process options for this RI/FS are included.

7.5.1 WAC for a Potential OSDC

The DFF&O established that a preliminary WAC be developed by DOE in the RI/FS and ultimately approved by Ohio EPA following community input. The WAC is comprised of seven components that serve as a series of evaluation criteria (or "gates"). A waste stream must pass through each gate before being allowed to be disposed in a potential OSDC. Some of the WAC components describe information that is needed or processes that must be followed and others are numerical standards that must be met. The details of the WAC components are developed at various stages of a project that is considering a potential OSDC. Some components can be defined in detail at the RI/FS stage of the project (such as prohibitions forbidding certain types of waste from being disposed). Other components would be defined in detail as the waste streams are better identified during development of other regulatory authority documents (for example a CAMU designation for the OSDC may include alternative treatment standards for CAMU-eligible waste). If a CAMU designation is approved by Ohio EPA, CAMU-based treatment standards for eligible waste would be adopted and incorporated into the WAC implementation process. And finally, other components are defined in detail as the design and operational requirements of a potential OSDC are refined.

The first WAC component, or gate, is the waste placement prohibitions that result from two mechanisms: (1) ARARs and (2) DOE operational decisions. All waste streams that are not allowed to be disposed in a potential OSDC are removed from further consideration. The prohibitions also include requirements such as treatment for certain types of waste that must be met prior to disposal. In these cases, the waste stream can pass through this gate once compliance with the requirements has been demonstrated.

Along with these prohibitions, the DFF&O defines the WAC in paragraph 5.mm as including six components: (1) activity criteria and chemical concentration criteria, (2) waste evaluation and characterization standards, (3) waste physical characteristics standards, (4) waste packaging standards, (5) waste safe handling standards, and (6) waste transportation standards. Waste streams that are allowed by law or by agreement to be placed in the potential OSDC would then need to be shown to be in compliance with the activity criteria and chemical concentration criteria discussed in Section 7.5.1.2. Once a waste stream has been shown to be allowed to be disposed by regulation or agreement, and it has been demonstrated that the waste stream meets the activity and chemical concentration criteria, a series of additional components or criteria must be met that ensure that the waste is appropriately characterized, is in the proper form for safe disposal, is appropriately packaged and transported, and is safe for workers must be met. The details of these components would be developed during completion of the design and operations plans of the potential OSDC. These concepts behind these components are discussed in Sections 7.5.1.3 through 7.5.1.7 along with current example requirements. Finally, Section 7.5.1.8 provides the proposed WAC which will form the basis for the final WAC that would be presented in the Proposed Plan for Ohio EPA approval, if an on-Site disposal alternative is selected. The final WAC will include numeric chemical limits based upon LDR considerations or with acceptable modifications for a CAMU if approved by Ohio EPA.

All required information to complete the details of each WAC component are available at different stages of the project. Table 7.2 presents the seven WAC components and discusses where the information on that component can be found in the waste disposition deliverables required under the DFF&O. These components are finalized in the Proposed Plan for Ohio EPA approval and will also be presented in the

ROD. As discussed above, some components of the WAC are dependent on completion of the design of a potential OSDC and consequently, may be refined through documentation in the DFF&O-required WAC Implementation Plan or OSDC Operations Plan (paragraph 15.b). The WAC Implementation Plan, per the DFF&O, is to be comprised of Waste Acceptance System Requirements, Waste Form Compliance Plan, and Waste Acceptance Delivery Schedules. The WAC Implementation Plan would provide the details of the WAC along with requirements for implementing the WAC. The OSDC Operations Plan would provide information on how the waste is to be transported, packaged, and safely received and placed.

Table 7.2. WAC Deliverables

WAC Component (paragraph 5.mm)	Description	Deliverable
ARAR and Operational-based Waste Prohibitions	1) Describes waste that cannot be accepted into an OSDC due to ARARs, and 2) decisions made based on operational needs.	Draft in RI/FS. Ohio EPA approved in Proposed Plan and ROD.
Activity Criteria (and removable and fixed radionuclide levels - paragraph 6.ff.3) and Chemical Concentration Criteria	Describes ARAR-specific criteria and performance-based WAC based on fate and transport modeling.	Draft in RI/FS. Numerical WAC for Ohio EPA approval in Proposed Plan and ROD. DOE will modify criteria based on hazardous waste regulations/ actions, including utilizing alternative treatment standards developed pursuant to a CAMU authorization/designation for a potential OSDC.
Waste Evaluation and Characterization Standards	Describes the characterization and documentation needed to demonstrate compliance with the WAC prior to, during, and after D&D, excavation, and/or treatment activities.	Draft in RI/FS. Ohio EPA approved in Proposed Plan and ROD. Modifications based on final design would occur during post-ROD design submittals. Final waste evaluation and characterization standards documented in WAC Implementation Plan (post-ROD) (paragraph 15.b).
Waste Physical Characteristics Standards (and physical structure - paragraph 6.ff.3)	Describes the physical size and condition that waste must have, including limit of void space, decomposability, compatibility, and appropriate EC-1/EC-2 waste ratio to meet ARARs and support operations.	Draft in RI/FS. Ohio EPA approved in Proposed Plan and ROD. Modifications based on final design would occur during post-ROD design submittals. Final waste physical characteristic standards documented in the OSDC Operations Plan (post-ROD) (paragraph 15.b).
Waste Packaging Standards	Describes any packaging allowances and requirements including those in ARARs.	Draft in RI/FS. Ohio EPA approved in Proposed Plan and ROD. Modifications based on final design would occur during post-ROD design submittals. Final waste packaging standards documented in OSDC Operations Plan (post-ROD) (paragraph 15.b).

Table 7.2. WAC Deliverables (Continued)

WAC Component (paragraph 5.mm)	Description	Deliverable
Waste Safe Handling Standards	Describes how release potential and hazards associated with the waste are to be managed during operation.	Draft in RI/FS. Ohio EPA approved in Proposed Plan and ROD. Modifications based on final design would occur during post-ROD design submittals. Final waste safe handling standards documented in WAC Implementation Plan (post-ROD) (paragraph 15.b).
Waste Transportation Standards	Describes how the waste can be transported across PORTS and to an on- or off-Site disposal location safely and in compliance with ARARs.	Draft in RI/FS. Ohio EPA approved in Proposed Plan and ROD. Modifications based on final design would occur during post-ROD design submittals. Final waste transportation standards documented in OSDC Operations Plan (post-ROD) (paragraph 15.b).

ARAR = applicable or relevant and appropriate requirement
CAMU = Corrective Action Management Unit
D&D = decontamination and decommissioning
DOE = U.S. Department of Energy
EC = engineering category
Ohio EPA = Ohio Environmental Protection Agency
OSDC = on-Site disposal cell
PORTS = Portsmouth Gaseous Diffusion Plant
RI/FS = Remedial Investigation/Feasibility Study
ROD = Record of Decision
WAC = waste acceptance criteria

7.5.1.1 ARAR and operational-based waste placement prohibitions

The ARARs/TBCs listed in Appendix F define regulatory and guidance-based requirements that must be addressed in the finalization of the WAC for any potential OSDC. These ARARs identify a number of waste types that are not allowed to be disposed in a potential OSDC at PORTS. In addition, DOE has included two prohibitions for operational reasons. All of these prohibitions are presented in Table 7.3. These materials would be excluded from on-Site disposal unless a waiver or exemption is granted or, where appropriate, the waste is treated or rendered to meet the requirement.

Table 7.3. ARAR and Operational-based Waste Placement Prohibitions

Prohibition	Rationale
A prohibition on the acceptance of waste from off-PORTS generating sources (excluding lab returns and treatability testing wastes and material currently stored on-Site).	Decision based on DFF&O requirements.
A prohibition on X-326 converters, compressors, and coolers.	DOE operational decision.
Containerized nuclear material inventories of uranium compounds exhibiting enrichments greater than 20 percent (excludes items such as miscellaneous parts, pipes, valves, empty containers etc., with only residual contamination which were packaged for ease of handling and safety reasons).	DOE operational decision made to add to safety factor for long-term protectiveness.
A prohibition on the acceptance of hazardous waste that does not meet LDR treatment standards.[a]	*40 CFR* 268.40(a) *OAC* 3745-270-40(A)

Table 7.3. ARAR and Operational-based Waste Placement Prohibitions (Continued)

Prohibition	Rationale
A prohibition on the acceptance of RCRA hazardous debris and/or soil that does not meet Alternate Treatment Standards.[a]	*40 CFR* 268.45(a) (for hazardous debris) *40 CFR* 268.49(a) (for hazardous soil) *OAC* 3745-270-45(A) (for hazardous debris) *OAC*3745-270-49(A) (for hazardous soil)
If a CAMU designation is approved, a prohibition on RCRA hazardous waste that does not meet the established minimum treatment standards for the Principal Hazardous Constituents.[a]	*40 CFR* 264.552(e)(4) *OAC* 3745-57-72(E)(4)
A prohibition on the acceptance of ignitable and reactive waste per RCRA.	*40 CFR* 264.312(b) *OAC* 3745-57-12(B)
A prohibition on the acceptance of TRU waste or HLW.	DOE Order 435.1 design constraints.
A prohibition on the acceptance of refrigeration equipment with remaining refrigerant per Ozone Standards.	40 *CFR* 82.154(b)
A prohibition on the placement of acid batteries.	40 *CFR* 273.31 *OAC* 3745-273-31
A prohibition on the placement of bulk used oils in liquid form.	40 *CFR* 279.81 *OAC* 3745-279-81
Prohibition on the disposal of PCB-contaminated electrical equipment (except capacitors) containing free-flowing liquids.	40 *CFR* 761.60(b)(4)
Prohibition on the disposal of PCB-contaminated articles containing free flowing liquids.	40 *CFR* 761.60(b)(6)(ii)
Prohibition on the disposal of PCB liquids drained from electrical equipment.	Must be disposed in an incinerator or high-efficiency boiler depending on concentration.
Waste must not be pyrophoric. Pyrophoric materials contained in waste shall be treated, prepared, and packaged to be nonflammable.	*OAC* 3701:1-54-1O(B)(6)
Waste must not be readily capable of detonation or of explosive decomposition or reaction at normal pressures and temperatures, or of explosive reaction with water.	*OAC* 3701:1-S4-1O(B)(4)
Waste must not contain or be capable of generating quantities of toxic gases, vapors, or fumes harmful to persons transporting, handling, or disposing of the waste.	*OAC* 3701:1-S4-10(B)(S)
Prohibition on the acceptance of RCRA hazardous waste containing bulk or noncontainerized liquid hazardous waste or hazardous waste containing free liquids (whether or not sorbents have been added).	40 *CFR* 264.314(a) *OAC* 3745-27-19(E)(8)(b) and (h)(i)

Table 7.3. ARAR and Operational-based Waste Placement Prohibitions (Continued)

Prohibition	Rationale
Prohibition on the placement of bulk or noncontainerized liquid hazardous waste or free liquids contained in hazardous waste (whether or not sorbents have been added) in any CAMU except where placement of such wastes facilitates the remedy selected for the waste. (This prohibition applies to CAMU eligible RCRA hazardous waste.)	40 *CFR* 264.552(a)(3) *OAC* 3745-57-72(A)(3)

[a] Any waste stream considered a hazardous waste must meet the applicable LDR treatment standards pursuant to the hazardous waste regulations. DOE is anticipating pursuing a CAMU designation for CAMU-eligible wastes via the forthcoming future Ohio Consent Decree document(s). The CAMU designation offers the opportunity to pursue adjusted treatment levels for principal hazardous constituents subject to Ohio EPA Director's approval based on certain criteria, including but not limited to the long-term protection offered by the engineering design of the potential OSDC. If the CAMU designation is approved by Ohio EPA, the treatment standards discussed in Section 7.5.1.2 would be adjusted accordingly.

CAMU = Corrective Action Management Unit
CFR = Code of Federal Regulations
DFF&O = *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto*
DOE = U.S. Department of Energy
HLW = high-level waste
LDR = land disposal restriction
OAC = Ohio Administrative Code
Ohio EPA = Ohio Environmental Protection Agency
OSDC = on-Site disposal cell
PCB = polychlorinated biphenyl
PORTS = Portsmouth Gaseous Diffusion Plant
RCRA = Resource Conservation and Recovery Act of 1976, as amended
TRU = transuranic

A number of regulations include a prohibition or restriction on the disposal of free liquids. If a material that arrives at the OSDC for disposal is too wet for proper placement, the material would be processed before placement per procedures identified in post-ROD DFF&O documents.

7.5.1.2 Activity- or chemical concentration-based waste acceptance criteria

The protectiveness of placement of the types of wastes found at DOE PORTS in an OSDC was evaluated using fate and transport analyses developed in accordance with the *Work Plan for Modeling Analysis in Support of Regulatory Decisions at the Portsmouth Gaseous Diffusion Plant, Piketon, Ohio* (DOE 2011f). This evaluation yielded results that validate the acceptability of an OSDC, designed using available engineering methods coupled with geologic controls, to prevent undue migration of chemical constituents at activity or concentration levels reasonably expected to be found during D&D activities.

Modeled WAC were developed for Study Area D, which is located entirely over the thick shale of the Cuyahoga Formation. This formation offers very low hydraulic conductivity, thus significantly retarding the vertical movement of water to lower geologic strata (i.e., Berea sandstone). A new site-specific, three-dimensional, vadose-zone numerical model was developed using field and laboratory data from Study Area D. This model is the principal basis for the fate and transport analysis of PORTS-related constituents found in buildings, soil, groundwater, and/or landfills.

The modeled fate and transport results for potential receptor locations are presented in this FS (Appendix I) and evaluate potential risk to human receptors based on achieving the following cumulative performance requirements:

- For carcinogens, the ELCR for the protection of human health is to be $\leq 1\times10^{-5}$ for the first 1,000 years after capping at any considered points of assessment.

- For noncarcinogens, the HI for the protection of human health is to be ≤ 1 for the first 1,000 years after capping at any considered points of assessment.

- Protection of ecological species at any point of surface discharge for the first 1,000 years after capping.

- Protection of the aquifer to MCLs at the downgradient edge of the potential OSDC waste for the first 1,000 years after capping.

The 1,000-year after capping time of compliance is identified in the DFF&O and consistent with DOE Manual 435.1-1, *Radioactive Waste Management*, Chapter IV, paragraph P(2) (DOE 2001c). DOE Order 458.1(4)(h)(1)(d)(1)(a) contemplates a compliance period of 200 to 1,000 years.

The fate and transport modeling produced an activity or concentration for every constituent at location where contamination was projected to migrate from the potential OSDC in potential groundwater, surface water, and air pathways up to 1,000 years. The model then projected the maximum acceptable concentration or activity in the potential OSDC for every potential constituent that resulted in an acceptable activity or concentration at the location, per the above listed requirements. These maximum possible and acceptable concentrations or activities found in the modeled portion of the WAC (modeled WAC) are presented in Appendix I.

The modeled WAC were calculated based on the hydrogeologic and geochemical characteristics of the potential OSDC planned location (Study Area D), in conjunction with the nature of the known waste contaminants and the design features of the potential OSDC. These factors act together to provide a high level of certainty that the contaminants present in waste streams at PORTS, regardless of the actual measured concentration in the waste stream, would not adversely impact human and environmental receptors above established regulatory limits within a 1,000-year design horizon. The range of activities or concentrations of the primary contaminants anticipated to be present in the PORTS waste streams are actually much lower than the calculated values in Appendix I, offering a substantial added safety factor to the expected long-term performance of the potential OSDC.

DOE has elected not to pursue on-Site disposal in any future OSDC of the following waste streams at PORTS:

- Converters, compressors and coolers from the X-326 Process Building

- Containerized nuclear material inventories of uranium compounds exhibiting enrichments greater than 20 percent (excludes miscellaneous parts, pipes, valves, etc., with residual contamination which were packaged for ease of handling and safety reasons).

While these streams are within the calculated values from Appendix I, they are, by agreement not being considered for on-Site disposal. With the elimination by agreement of the waste streams listed in the bullets above, use of a potential OSDC for the remaining waste materials present at PORTS would create a modeled safety factor of at least five orders of magnitude, providing substantial added assurance that no human or ecological receptor would be impacted above established regulatory levels within the 1,000-year design horizon.

Other regulatory requirements. There are other regulatory requirements that would result in activity and chemical concentration criteria that must be met by any waste stream considered for disposal in a potential OSDC. Prior to land disposal, all hazardous wastes must meet treatment standards. Treatment standards, arranged by hazardous waste code, are located in the “Treatment Standards for Hazardous Waste” table in *OAC* rule 3745-270-40 for hazardous waste, in *OAC* rule 3745-270-45 for hazardous waste contaminated debris, and in *OAC* rule 3745-270-49 for hazardous waste contaminated soil. Treatment standards can be expressed as concentration-based values or as specific treatment technologies. Concentration-based treatment standards, which, depending on the waste are either a concentration in the waste or in a waste extract, appear in the table as numeric values. An example treatment standard would be 60 mg/kg (10 times the universal treatment standard) for TCE in soil or 90 percent reduction in total constituent concentration, whichever is greater, under *OAC* rule 3745-270-49. When the use of a specific technology is required, the standard is expressed as a five-letter code. These specified technologies are described in *OAC* rule 3745-270-42.

Depending on the hazardous waste code, the treatment standards may be met by either of the following:

- Ensuring all hazardous constituents in the waste or treatment residue are at or below the total concentration values based on total constituent analysis (total waste standards) or a TCLP analysis (waste extract standards), whichever is applicable

- Treating the hazardous constituents in the waste or treatment residue to at or below the values based on total constituent analysis (total waste standards) or a TCLP analysis (waste extract standards), whichever is applicable

- Treating the hazardous waste by using a specific treatment technology (technology standards) when applicable.

DOE is anticipating pursuing a CAMU designation for CAMU-eligible wastes via the forthcoming future Ohio Consent Decree document(s). The CAMU designation offers the opportunity to pursue adjusted treatment levels for principal hazardous constituents subject to Ohio EPA Director’s approval based on certain criteria, including but not limited to the long-term protection offered by the engineering design and favorable geology of the potential OSDC. Ohio Consent Decree document(s) will serve as the mechanism for Ohio EPA to approve of the list of principal hazardous constituents and corresponding adjusted treatment levels for the CAMU. Any adjusted values would be used for the residual soils (RC-1, EC-1), deferred unit soils (RC-2, EC-1), and the waste excavated for use as fill from PORTS existing landfills (RC-3, EC-1 and EC-2) and selected groundwater contamination areas (RC-2, EC-1).

7.5.1.3 Waste evaluation and characterization standards

These standards define requirements for determining the waste type and determining compliance with WAC, including chemical and physical analysis and/or information which must be known to treat, store, or dispose of the waste in accordance with state solid and hazardous waste requirements, RCRA, TSCA, and DOE LLW requirements.

The establishment of these standards is based on the requirements of the final OSDC design. The DFF&O establishes a requirement for a design deliverable called a WAC Implementation Plan. The WAC Implementation Plan, per the DFF&O, paragraph 15.b, is to be comprised of Waste Acceptance System Requirements, Waste Form Compliance Plan, and Waste Acceptance Delivery Schedules. The plan would evaluate each of the approved ARAR/TBCs relevant to waste evaluation and characterization and present a compliance approach aligned with the final OSDC design. Upon approval and/or concurrence, as appropriate, by Ohio EPA, the WAC Implementation Plan would become an enforceable part of the WAC.

7.5.1.4 Waste physical characteristics

Waste physical characteristics define the physical form of waste and requirements for filling voids within waste or around waste to ensure stability after placement such that the waste does not structurally degrade and effect overall stability of the waste through slumping, collapse, or other failures of a potential OSDC and thereby lead to water infiltration through the cover systems. Physical limits of size, shape and distance to the liner are also set to prevent potential damages to the bottom liner materials of a potential OSDC that may lead to leaks through the liner systems. Also, waste physical characteristics define the limitations on waste forms including dimensions, thickness, and weight limitations of waste items and packages based on operational constraints including methods of waste handling such as conveyance, off-loading, material placement, and waste compaction. The details of the waste physical characteristics will be developed consistent with the conveyance and material handling equipment selected for use at a potential OSDC. Table 7.4 presents typical waste physical characteristics.

Table 7.4. Typical Waste Physical Characteristics

Description	Typical Waste Physical Characteristics[a]
Maximum length of irregularly shaped metals or other components of a building superstructure or finished component	10 ft (or 12 ft for transite panels)
Maximum thickness of irregularly shaped metals or other components of a building superstructure or finished component	18 in.
Maximum thickness of an individual concrete member or other component of a building slab or substructure	4 ft
Concrete reinforcement bars	Rebar shall be cut 12 in., nominally, from the concrete mass
Maximum thickness of uniform pallets of building cladding (e.g., transite panels which are to be properly banded)	4 ft
Piping with a nominal diameter of 12 in. or greater	Split in half, longitudinally; crushed; nested with pipes of smaller diameters; or filled with quick set grout or flowable, cohesionless material
Waste items not conducive to size reduction and having internal voids greater than 1 cf	Voids to be filled with quick set grout or flowable, cohesionless material prior to final disposal; or to be placed in whole by encasing with concrete from outside[b]
Pressurizable gas cylinders (i.e., gas cylinders that are still mechanically able to be pressurized)	Shall be rendered unpressurized prior to disposal
Intact empty drums	Crushed to eliminate void space

[a] Examples from other facility WAC. The final list will be part of the OSDC Operations Plan.
[b] Pending final engineering design.

OSDC = on-Site disposal cell
WAC = waste acceptance criteria

The DFF&O requires the submittal of an OSDC Operations Plan. This design deliverable will refine these physical characteristic standards. The Plan will analyze each of the approved ARAR/TBCs relevant to the establishment of limitations on the physical characteristics of the waste for acceptance into the potential OSDC. The Operations Plan demonstrates how the planned physical WAC and final design-based waste placement approach complies with each of these ARAR/TBCs. Upon approval and/or concurrence, as appropriate, by Ohio EPA, the OSDC Operations Plan would become an enforceable part of the WAC.

7.5.1.5 Waste packaging standards

These standards define the type of containers that may be used for on-Site waste transport and disposal. They must be compatible with the waste contained in order to protect workers and the public during transport and disposal. A vast majority of waste is to be transported and disposed as uncontainerized bulk waste. However, for some waste streams, containers (i.e., B-25 boxes, 20 cy roll-off containers, drums, soft-sided bags) may be used. If used, these containers must be structurally capable of containing the waste, must be 90 percent full when placed in a potential OSDC, may not contain free liquids in excess of 1 percent by volume, and must be placed in a manner that maintains the package integrity, minimizes void space between packages, and permits the void spaces to be filled. Also, regulated ACM must be adequately wetted, collected, and sealed in leak-proof containers. Waste packaging standards for waste disposal are reliant on the final design and operation methods of the potential OSDC. Table 7.5 presents potential waste packaging standards.

Table 7.5. Potential Waste Packaging Standards

Requirement	Basis
Regulated asbestos-containing material (RACM) (e.g., pipe lagging, insulation, ceiling tiles) shall be adequately wetted, collected, and sealed in leak-proof containers.	*OAC* 3745-20-05(C)
Beryllium-contaminated equipment shall be disposed in sealed, impermeable bags, containers, or enclosures to prevent release during handling and transportation.	Chronic Beryllium Disease Prevention Program 10 *CFR* 850.31(c)(3)
Beryllium-containing bags, containers, and enclosures shall be labeled accordingly.	Chronic Beryllium Disease Prevention Program 10 *CFR* 850.31(a)

CFR = Code of Federal Regulations
OAC = Ohio Administrative Code

The above-referenced OSDC Operations Plan will define the requirements for placement of bulk and containerized waste based upon the final design. This design deliverable would establish the packaging requirements for such waste to render it acceptable for transport or disposal. The Plan will evaluate each of the approved ARAR/TBCs and present standards and a waste placement approach that demonstrates compliance with these ARAR/TBCs. Upon approval and/or concurrence, as appropriate, by Ohio EPA, the OSDC Operations Plan would become an enforceable part of the WAC.

7.5.1.6 Waste safe handling standards

These standards define limitations on waste that are protective of workers involved in the handling of waste during receipt at a potential OSDC, as described in 10 *CFR* 835, *Occupational Radiation Protection*. Waste safe handling standards developed for a potential OSDC include requirements to package waste commensurate with analyzed hazards such as dose rates associated with handling routine contact-handled packages as well as bulk disposal conveyances (e.g., dump trucks), and requirements to containerize asbestos to prevent air borne releases. Safe handling standards will follow requirements from the DOE concept that all radiological operations employ “as low as reasonably achievable” (ALARA) practices to keep worker doses well below applicable dose standards. These components provide the appropriate level of protectiveness related to safe handling of waste. The waste safe handling standards would be finalized through the OSDC Operations Plan incorporating the results of the hazards analysis process. This plan would also evaluate each of the approved ARAR/TBCs and factor the relevant regulatory requirements into the finalization of the standards. Upon approval and/or concurrence, as appropriate, by Ohio EPA, the OSDC Operations Plan would become an enforceable part of the WAC.

7.5.1.7 Waste transportation standards

This is a defined component of the WAC pursuant to the DFF&O and would establish the requirements for the safe movement of waste to a potential OSDC to protect the environment and workers from spillage and to provide plans to control spills. Such standards are a result of the final design process based on the approved physical characteristic standards and operations approach. Table 7.6 presents the waste transportation standards anticipated.

Table 7.6. Waste Transportation Standards

Requirement	Basis
Radioactive waste shall be packaged and moved in accordance with substantive requirements of DOE Order 460.1C (*Packaging and Transportation Safety*).	DOE Order 460.1C
Cover at all times, open-bodied vehicles when transporting materials likely to become airborne.	*OAC* 3745-17-08(B)(7)

DOE = U.S. Department of Energy
OAC = Ohio Administrative Code

Agreed upon TBC DOE Order 460.1c (4) (b) requires the development and compliance with facility-specific Transportation Safety Documents for movement of material or waste on the plant. The DFF&O-required Operations Plan will present the final transportation standards based upon the DOE-required Transportation Safety Document and an analysis of each of the relevant approved ARAR/TBCs. Upon approval and/or concurrence, as appropriate, by Ohio EPA, the OSDC Operations Plan would become an enforceable part of the WAC.

7.5.1.8 Proposed WAC

The WAC is comprised of the following seven components: (1) prohibitions resulting from ARARs and DOE operational decisions, (2) activity criteria and chemical concentration criteria, (3) waste evaluation and characterization standards, (4) waste physical characteristics standards, (5) waste packaging standards, (6) waste safe handling standards, and (7) waste transportation standards. A waste stream must meet each component before being allowed to be disposed in a potential OSDC.

The first WAC component (see Table 7.7) is waste placement prohibitions that result from two mechanisms: (1) ARARs and (2) DOE operational decisions. All waste streams that are not allowed to be disposed in a potential OSDC as a result of one of these prohibitions are removed from further consideration. The list of draft prohibitions is presented in Table 7.7. No additional information is needed from the design of a potential OSDC to finalize the draft prohibitions.

Then each waste stream is evaluated against the activity and chemical concentration criteria and those that do not meet the criteria are not allowed to be disposed in a potential OSDC unless further treatment pursuant to defined requirements is performed. Groundwater fate and transport modeling along with an evaluation of potential contaminant concentrations likely to be present in D&D waste (RC-1) and other waste (RC-2, RC-3, RC-4) streams indicates that there is a five order of magnitude safety factor between resultant protective numerical levels and the concentrations in the waste streams. This conclusion is primarily due to the favorable geologic conditions found at the proposed location of a potential OSDC along with the design elements of the cells.

However, any waste stream considered a hazardous waste must meet the treatment standards outlined in Table 7.7. DOE anticipates pursuing a CAMU designation for CAMU-eligible wastes via the forthcoming future Ohio Consent Decree document(s). The CAMU designation offers the opportunity to pursue adjusted treatment levels for principal hazardous constituents subject to Ohio EPA Director’s approval based on certain criteria, including but not limited to, the long-term protection offered by the engineering design of the potential OSDC. If a CAMU designation is approved, the treatment standards discussed in Table 7.7 would be adjusted accordingly. There is no information being generated during the design of the potential OSDC that is needed to finalize these draft activity and chemical concentration criteria presented in Table 7.7.

The other components of the WAC would be modified as further design and operations plans are developed. Table 7.7 presents the two design and operations documents that, upon Ohio EPA review and approval and/or concurrence, would become an enforceable part of the ROD should an on-Site alternative be selected. These documents will detail out the remaining WAC components defined in the DFF&O.

Table 7.7. Proposed WAC for a Potential OSDC

Prohibitions	
Prohibition/Exclusions	**Rationale**
A prohibition on the acceptance of RCRA hazardous waste that does not meet LDR treatment standards.	*40 CFR* 268.40(a) *OAC* 3745-270-40(A)
A prohibition on the acceptance of RCRA hazardous debris and/or soil that does not meet Alternate Treatment Standards.	*40 CFR* 268.45(a) (for hazardous debris) *40 CFR* 268.49(a) (for hazardous soil) *OAC* 3745-270-45(A) (for hazardous debris) *OAC*3745-270-49(A) (for hazardous soil)
If a CAMU designation is obtained, a prohibition on CAMU-eligible RCRA hazardous waste that does not meet the established minimum treatment standards for the Principal Hazardous Constituents.	*40 CFR* 264.552(e)(4) *OAC* 3745-57-72(E)(4)
A prohibition on the acceptance of ignitable and reactive waste per RCRA.	*40 CFR* 264.312(b) *OAC* 3745-57-12(B)
A prohibition on the acceptance of TRU waste or HLW.	DOE Order 435.1 design constraints.
A prohibition on the acceptance of refrigeration equipment with remaining refrigerant per Ozone Standards.	40 *CFR* 82.154(b)
A prohibition on the placement of acid batteries.	40 *CFR* 273.31 *OAC* 3745-273-31
A prohibition on the placement of bulk used oils in liquid form.	40 *CFR* 279.81 *OAC* 3745-279-81
Prohibition on the disposal of PCB-contaminated electrical equipment (except capacitors) containing free-flowing liquids.	40 *CFR* 761.60(b)(4)
Prohibition on the disposal of PCB-contaminated articles containing free flowing liquids.	40 *CFR* 761.60(b)(6)(ii)
Prohibition on the disposal of PCB liquids drained from electrical equipment.	Must be disposed in an incinerator or high-efficiency boiler depending on concentration.
Waste must not be pyrophoric. Pyrophoric materials contained in waste shall be treated, prepared, and packaged to be nonflammable.	*OAC* 3701:1-54-1O(B)(6)
Waste must not be readily capable of detonation or of explosive decomposition or reaction at normal pressures and temperatures, or of explosive reaction with water.	*OAC* 3701:1-S4-1O(B)(4)
Waste must not contain or be capable of generating quantities of toxic gases, vapors, or fumes harmful to persons transporting, handling, or disposing of the waste.	*OAC* 3701:1-S4-10(B)(S)
Prohibition on the acceptance of RCRA hazardous waste containing bulk or noncontainerized liquid hazardous waste or hazardous waste containing free liquids (whether or not sorbents have been added).	40 *CFR* 264.314(a) *OAC* 3745-27-19(E)(8)(b) and (h)(i)

Table 7.7. Proposed WAC for a Potential OSDC (Continued)

Prohibitions	
Prohibition/Exclusions	**Rationale**
If a CAMU designation is obtained, prohibition on the placement of bulk or noncontainerized liquid hazardous waste or free liquids contained in hazardous waste (whether or not sorbents have been added) in any CAMU except where placement of such wastes facilitates the remedy selected for the waste. (This prohibition applies to CAMU eligible RCRA hazardous waste.)	40 *CFR* 264.552(a)(3) *OAC* 3745-57-72(A)(3)
Prohibited Waste Streams by Agreement	
Waste Stream	**Description**
Off-PORTS generated waste.	A prohibition on the acceptance of waste from off-PORTS generating sources (excluding lab returns and treatability testing wastes and material currently stored on the Facility).
Compressors, Converters, and Coolers from X-326.	Components in-place within the X-326 Process Building as of April 15, 2010, the initial date of the DFF&O.
Enriched materials.	Containerized nuclear material inventories of uranium compounds exhibiting enrichments greater than 20 percent (excludes items such as miscellaneous parts, pipes, valves, empty containers etc., with only residual contamination which were packaged for ease of handling and safety reasons).
Activity and Chemical Concentration Criteria	
Waste Stream	**Requirement**
Hazardous waste.	Treatment standards, arranged by hazardous waste code, are located in the "Treatment Standards for Hazardous Waste" table in *OAC* rule 3745-270-40.
Hazardous waste contaminated debris.	Alternate treatment standards are located in *OAC* rule 3745-270-45.
Hazardous waste contaminated soil.	Alternate treatment standards are located in *OAC* rule 3745-270-49.
Hazardous waste – CAMU designation.	If a CAMU designation for a potential OSDC is obtained, alternate treatment standards may be developed under future Ohio Consent Decree document(s) and may be used to replace those standards in 3745-270-40, 45, and 49.
Documents That Become Part of WAC Upon Approval/Concurrence	
Document[a]	**WAC Components Included (para. 5.mm)**
WAC Implementation Plan.	**Prohibitions** (carried forward from the ROD). **Activity Criteria and Chemical Concentration Criteria** (carried forward from the ROD). **Waste Evaluation and Characterization Standards** **Waste Safe Handling Standards.**
OSDC Operations Plan.	**Waste Physical Characteristics Standards** **Waste Packaging Standards** **Waste Transportation Standards.**

[a] The noted documents will become part of the enforceable WAC upon Ohio EPA review and approval and/or concurrence.

CAMU = Corrective Action Management Unit
CFR = Code of Federal Regulations
DFF&O = *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto*
DOE = U.S. Department of Energy
HLW = high-level waste
LDR = land disposal restrictions
OAC = Ohio Administrative Code
Ohio EPA = Ohio Environmental Protection Agency
OSDC = on-Site disposal cell
PCB = polychlorinated biphenyl
PORTS = Portsmouth Gaseous Diffusion Plant
RCRA = Resource Conservation and Recovery Act of 1976, as amended
ROD = Record of Decision
TRU = transuranic
WAC = waste acceptance criteria

7.5.2 WAC for Representative Off-Site Disposal Facilities

WAC for the three representative off-Site disposal process options are presented in this section. If other disposal options are selected during the design, those WAC will be obtained and shared with Ohio EPA.

Energy*Solutions* Waste Acceptance Criteria. The following LLW WAC are applicable:

- LLW (source material, special nuclear material [SNM], and 11.e[1] waste [SNM byproduct material]) with individual or mixture concentrations less than those listed in the Energy*Solutions* radioactive material license are accepted for disposal.

- Waste with activity greater than Class A per 10 *CFR* 61 is not accepted for disposal.

The following mixed waste WAC are applicable:

- All waste must meet RCRA treatment standards. Mixed waste is acceptable for disposal provided the concentrations of hazardous constituents do not exceed those outlined in 40 *CFR* 268. Wastes prohibited from land disposal per 40 *CFR* 268 are not accepted for disposal.

- The radionuclide concentrations acceptable in mixed waste are those specified for LLW.

- Asbestos and other TSCA waste is accepted for disposal with some limitations provided in the WAC.

The current Energy*Solutions* WAC for the Clive facility are documented in Energy*Solutions* (2011).

NNSS Waste Acceptance Criteria. The following LLW WAC are applicable:

- LLW with concentrations tied to activity “action limits” is accepted for disposal.

- Class A, B, or C waste per 10 *CFR* 61 is accepted for disposal. However, the NRC waste classification standards do not formally apply to DOE LLW.

- Waste must be certified for disposal under an approved NNSS Waste Certification Program.

The following mixed waste WAC are applicable:

- All waste must meet RCRA treatment standards. Mixed waste is acceptable for disposal provided the concentrations of hazardous constituents do not exceed those outlined in 40 *CFR* 268. Wastes prohibited from land disposal per 40 *CFR* 268 are not acceptable for disposal.

- The radionuclide concentrations acceptable in mixed waste are those specified for LLW.

The following general WAC are applicable:

- DOE classified waste (for security purposes) is accepted.
- Wastes containing free liquid are not acceptable for disposal.
- Waste must meet fissile gram quantity limitations provided in the WAC.
- Waste must meet plutonium gram quantity limitations provided in the WAC.
- NNSS can accept only DOE-generated waste and specific defense waste for disposal.

Pike Sanitation Landfill Waste Acceptance Criteria. Pike Sanitation Landfill accepts the following wastes for disposal at its landfill in Pike County:

- Construction debris

- Soil

- Demolition waste from facilities or soil known, by process knowledge and/or physical sampling, to have no regulated concentrations of radioactive and/or hazardous waste.

The following wastes are not accepted for disposal or treatment:

- LLW
- RCRA hazardous waste
- TSCA waste (PCB levels above 50 mg/kg)
- Liquid waste.

Pike Sanitation Landfill is prohibited from receiving any waste that contains technologically-enhanced, naturally-occurring radioactive material, by-product, source, or special nuclear material.

HIGHLIGHTS OF SECTION 7

- The three foundations for developing alternatives are: (1) regulatory understanding, (2) development of RAOs, and (3) identification of representative process options.
- All alternatives to be considered will be protective of human health and the environment and meet surface water and groundwater protection standards.
- A new on-Site engineered cell and three existing off-Site disposal locations along with on-PORTS fill and recycling and/or reuse are identified to represent the range of viable disposal process options in the development of the alternatives.

NEXT STEP: SECTION 8 DEVELOPS AND DESCRIBES A RANGE OF ALTERNATIVES THAT SOLVE THE PROBLEM

8. FINAL DEVELOPMENT OF ALTERNATIVES

Section 8 completes the identification of potential solutions. This section explains the assembly of representative process options into final remedial action alternatives, each aimed to achieve the RAOs and comply with ARARs/TBCs. These alternatives are developed in Section 8.1 and are based on the process options identified as representative process options from Section 7 and the volumes presented in Section 4. Section 8.2 then presents the action-specific ARARs/TBCs for each of the developed alternatives. These alternatives are then described in sufficient detail in Section 8.3 to support the evaluation of alternatives, including a cost estimate, in Section 9.

Three alternatives have been developed:

1) No Action
2) On-Site disposal with partial off-Site disposal
3) All off-Site disposal.

The no-action alternative assumes no disposal of any waste generated. The second alternative assumes a new on-Site disposal facility is built. Any waste not meeting the established WAC for a potential OSDC would be shipped off Site for disposal. And finally, the third alternative assumes all waste is shipped off Site for disposal.

8.1 DEVELOPMENT OF ALTERNATIVES

The following GRAs were identified in Section 7 to be developed into waste disposition alternatives:

- No Action
- Institutional Controls on a Potential OSDC
- Centralized Treatment
- On-Site Disposal
- Off-Site Disposal
- Recycling and/or Reuse
- Waste Transportation.

Three remedial alternatives are developed. They are a no-action alternative and two action alternatives, on-Site disposal and off-Site disposal. These alternatives represent an appropriate range of Site-wide disposition options, with one alternative leaving as much waste on Site as would meet a potential OSDC’s WAC. Any waste not meeting the established WAC for a potential OSDC would be shipped off Site for disposal. The other alternative takes all waste to an off-Site disposal location.

The on-Site alternative’s key aspect is construction of a new potential OSDC. The off-Site alternative’s key component is that all waste covered by this decision is disposed of in a properly licensed or permitted commercial or government facility.

A component of both the on-Site and off-Site alternatives is recycle and/or reuse of materials generated from the D&D activities in compliance with ARARs. For the purposes of evaluating remedial action alternatives, a consistent amount of recycling and/or reuse of D&D materials is assumed as part of each of the action-based alternatives. Preparation for recycling and/or reuse may include, but not be limited to, crushing, size reduction, segmentation, segregation, storage, decontamination, characterization and construction and operation of facilities to conduct and/or support such activities. Those activities done to prepare the material for recycle and/or reuse are generally evaluated as part of the Process Buildings and

Complex Facilities D&D Evaluation Project. In the event that recycling and/or reuse of materials requires the implementation of a large-scale centralized treatment process at PORTS, the evaluation would be part of the Site-wide Waste Evaluation Disposition Evaluation Project.

Below is a description of the remedial alternatives. Solely for purposes of the RI/FS evaluation, including the cost estimate, certain assumptions (e.g., use of new wastewater treatment systems) have been made, and the identified representative process options have been used to describe the alternative in more detail in Section 8.3. Specific methods may change during later phases of this project.

8.1.1 Alternative 1 – No Action

Alternative 1 is the no-action alternative based on the no-action GRA. The no-action alternative is required to establish and document baseline conditions and provide a basis for comparison to the other remedial action alternatives. This alternative would consist of no D&D of the PORTS buildings and no waste (RC-1) disposal. As discussed in Section 5, under no action, buildings would eventually degrade, resulting in releases of contaminants with migration to where exposures to human and ecological receptors may occur. Further, this alternative does not consider controls necessary to prevent access to the facilities and the associated physical hazards they present. The following are key components of this alternative:

- Buildings would not be demolished but instead would be left to degrade.

- No waste requiring management would be generated; therefore, associated radiological and hazardous constituents would remain on Site.

- No item would be recycled and/or reused.

- No S&M of the facilities to prevent degradation would occur.

- No institutional controls would be implemented to control access to radioactive or hazardous waste constituents.

8.1.2 Alternative 2 – On-Site Disposal

This alternative involves siting and constructing an engineered potential OSDC with operations of the facility for disposal of anticipated PORTS waste. Waste not meeting the facility WAC would be shipped to appropriate off-Site disposal facilities. Alternative 2 is comprised of the following GRAs:

- Institutional Controls on a potential OSDC
- Centralized Treatment[1]
- On-Site Disposal
- Off-Site Disposal
- Recycling and/or Reuse
- Waste Transportation.

Alternative 2 consists of a potential OSDC that would be designed, built, and operated to accept LLW (including classified waste), RCRA hazardous waste, TSCA waste, construction and demolition debris, solid waste, and combinations of these regulatory waste types, constructed using a multi-layered liner

---

[1] Centralized treatment in this context refers to significant, non-commercial, ARAR-compliant treatment efforts that may require additional DFF&O documentation.

system, and ultimately capped with a final multi-layered capping system designed to meet long-term infiltration requirements. Appendix D, the siting study, presents the information on candidate waste locations considered for this decision. As a result of that siting study, two candidate locations are considered to be viable for construction of a potential OSDC: Study Area C (the specific location is called Site C) and Study Area D (Site D). Additionally, Appendix D describes why Site D is selected for analysis to represent both Sites C and D (or any other location over similar geological conditions) for an on-Site disposal alternative. Recycling and/or reuse is also part of the alternative.

The following are key elements of this alternative:

- Establishment of final WAC (established for a potential OSDC) including concentration-based limits for the placement of discrete waste constituents in a potential OSDC so as to meet ARARs and to ensure the long-term protectiveness of human health and the environment, including groundwater resources at the downgradient edge of the facility.

- Transportation and disposal of D&D waste (RC-1) meeting the WAC in a potential OSDC, with waste not meeting the WAC either treated (through this project or through the waste generating project) or shipped and disposed of off Site at disposal facilities approved for receipt of such waste.

- Transportation and disposal of some non-radiologically contaminated and nonhazardous D&D waste (RC-1) within a potential OSDC or at an appropriately permitted local, off-Site solid waste disposal facility.

- Construction and operation of centralized size reduction or decontamination processes and/or staging of recovered materials in support of recycling and/or reuse initiatives in compliance with ARARs.

- Design, construction, and operation of a potential OSDC satisfying both design-based and performance-based requirements of DOE and other substantive requirements and guidance developed and documented in the ARARs/TBCs for the on-Site alternative. A potential OSDC is envisioned to be built in modular fashion with individual lining systems so as to ensure sufficient available capacity is available to support D&D activities, but without the program risk of developing disposal capacity that would not be used.

- The infrastructure supporting a potential OSDC would include wastewater treatment designed for the waste constituents and throughput from anticipated leachate from any on-Site landfill operations as well as other wastewaters that may be generated.

- Haul roads appropriate to transport waste from the generation area to a potential OSDC would be built.

- Fill material, for purposes of supporting waste placement in a potential OSDC, is anticipated to be from on- and/or off-PORTS borrow locations. Fill is always designated as having soil-like properties and therefore is categorized as EC-1. When considering cell operations, all waste requiring fill to reduce void spaces is considered as one type (EC-2).

- The infrastructure supporting a potential OSDC would include a waste staging area where waste could be held on a non-permanent basis, such as when operations at a potential OSDC have been suspended for weather. This staging area would provide for the staging of waste for logistics purposes to support the optimal mixture of waste requiring fill (EC-2) and soil (EC-1) at a potential OSDC.

- The alternative includes the appropriate institutional controls at a potential OSDC to prevent access to the waste in the future.

- Long-term maintenance, surveillance, and monitoring are included.

The presence of a potential OSDC would provide the potential for wastes generated through the conduct of PORTS cleanup activities outside of the DFF&O (RC-2, RC-4) to be disposed in that potential OSDC. Such waste could include non-DFF&O environmental media and other materials generated during cleanup activities (RC-2).[2]

8.1.3 Alternative 3 – Off-Site Disposal

Under this alternative, anticipated waste would be disposed off Site at disposal facilities approved to accept DOE-generated waste. As discussed in Section 4, 1.47 million cy of waste (RC-1), including 53,000 cy of residual soil (RC-1, EC-1), anticipated to be generated under the Process Buildings and Complex Facilities D&D Evaluation Project and earlier DFF&O removal actions would require packaging, transportation, and disposition off Site. The DOE-approved off-Site disposal facilities could be either a DOE disposal facility and/or commercial facilities authorized to accept LLW, TSCA waste, hazardous waste, and/or construction and demolition debris and solid waste. The facilities considered could also include recycling and/or reuse facilities.

Alternative 3 is comprised of the following GRAs:

- Centralized Treatment[3]
- Off-Site Disposal
- Recycling and/or Reuse
- Waste Transportation.

Key elements of this alternative include the following:

- Most waste anticipated to be generated by PORTS D&D projects (RC-1) would be managed as a radioactive, hazardous, construction and demolition debris, solid, and/or TSCA (PCB) waste and would be transported and dispositioned at off-Site approved DOE and commercial disposal facilities.

- Waste (RC-1) that did not require management as either a radioactive and/or hazardous waste would be shipped and disposed at an off-Site local solid waste landfill, as appropriate.

- Both off-Site disposal and transportation, be it by truck or rail, are part of this alternative.

- Infrastructure upgrades such as to the rail yard would be implemented.

---

[2] The DFF&O RI/FS SOW Section 3.5.1 states "Respondent shall collect the following data: B. Potential waste streams associated with environmental media cleanup activities to be conducted under the RCRA Consent Decree and for which DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste stream in any OSDC that might be constructed as a result of the Site-Wide Waste Disposition Evaluation project."

[3] Centralized treatment in this context refers to significant, non-commercial, ARAR compliant treatment efforts that may require additional DFF&O documentation.

- Centralized size reduction or decontamination of materials and staging of recovered materials in support of recycling and/or reuse, as well as recycling in compliance with ARARs.

8.2 SUMMARY OF ACTION-SPECIFIC ARARS/TBCS FOR EACH ALTERNATIVE

Action-specific ARARs/TBCs include operation, performance, and design requirements or limitations based on the waste types, media, and removal/remedial activities.

8.2.1 Alternative 1

Pursuant to EPA guidance, there are no ARARs/TBCs for a no-action alternative (EPA 1991).

8.2.2 Alternative 2

The action-specific ARARs and TBCs identified in Appendix F address design, construction, operation, capping, and post-operations care for the potential on-Site disposal alternative. Alternative 2 would be completed in compliance with the substantive portions of all design, construction, operation, capping, and post-operation care ARARs. These ARARs include landfill design and operation requirements under the federal TSCA for chemical waste disposal facilities; federal and state requirements under Subtitle C of RCRA, as amended, for hazardous waste disposal facilities; DOE Manual 435.1-1 requirements for LLW disposal facilities; state requirements under *OAC* 3745-27 for solid waste landfills; and federal and state Clean Air Act of 1970 (CAA) requirements for ACM disposal facilities.

The ARARs applicable to the disposal of wastes in an on-Site disposal facility include the requirements for a RCRA hazardous waste landfill (40 *CFR* 244 and *OAC* 3745-57) and a TSCA chemical waste landfill in 40 *CFR* 761.75. Further, the TSCA-related ARARs for chemical waste landfill design requirements generally follow the RCRA landfill design requirements. The TSCA ARARs, however, specify that if a synthetic liner is used, it must have a minimum thickness of 30 mil. In addition, they specify that the bottom of the liner must be located 50 ft above the historical high groundwater mark and must prohibit any hydrologic connection between the waste and any surface water (40 *CFR* 761.75[b][3]).

All primary wastes (concrete, PGE, asbestos, other building waste, and soil [RC-1]) and secondary wastes (such as contaminated PPE, decontamination wastes) generated during facility construction and operation activities must be appropriately characterized and managed in accordance with RCRA, TSCA, DOE Orders, CAA, or other requirements as specified in the ARARs/TBCs (Appendix F). Hazardous waste determinations would be based on available process knowledge and/or sampling/analysis results.

Wastewater generated at a potential OSDC is assumed to be treated on Site for constituents expected to be present in leachate, contaminated storm water, and other wastewater generated. If effluent is discharged via the existing NPDES permitted outfall, effluent would be discharged and monitored in accordance with the existing NPDES permit. If the existing NPDES permit needs to be modified, DOE would seek modification from Ohio EPA. If effluent is discharged to surface water via a new outfall (not associated with the existing NPDES permit), it would be discharged compliant with substantive ARAR requirements and limits would be submitted to Ohio EPA for approval or concurrence, as applicable, to ensure applicable limits found in permitting rules are established. It is assumed that the wastewater treatment system would emit less than 10 lb per day of air contaminants in compliance with the de minimis emission limits of *OAC* 3745-15-05(B).

It is anticipated that most treatment to meet the WAC, as deemed necessary, would be the decided by the project decision documents generating the waste, even if it takes place within a potential OSDC boundary. The exception would be the use of centralized size reduction and decontamination facilities that may be used across several waste-generating projects, as described in Section 7, to either support compliance with WAC or to support recycling and/or reuse. These centralized size reduction and decontamination facilities and associated ARARs are included in this alternative. A potential OSDC would be responsible for any necessary treatment and/or off-Site transport of secondary wastes it generates during facility operations that could not meet the WAC for on-Site disposal.

To remove the disincentives to cleanup that the application of stringent RCRA LDRs and treatment standards to remediation wastes can impose, EPA has promulgated rules establishing CAMUs under RCRA to facilitate treatment, storage, and disposal of hazardous remediation wastes. These rules establish minimum design and operating standards for CAMUs and minimum treatment standards for wastes placed in CAMUs (CAMU-eligible wastes) in place of meeting LDRs. The rules also allow for mixing and blending of wastes in staging piles, and similar physical operations intended to prepare waste for subsequent management and treatment, and have a provision allowing off-Site placement of CAMU-eligible waste in hazardous waste landfills.

DOE is anticipating pursuing a CAMU designation for CAMU eligible wastes via future Ohio Consent Decree document(s). The CAMU designation offers the opportunity to pursue adjusted treatment levels for principal hazardous constituents subject to Ohio EPA Director's approval based on certain criteria, including but not limited to the long-term protection offered by the engineering design of a potential OSDC. The Ohio Consent Decree document(s) would serve as the mechanism for Ohio EPA to approve of the list of principal hazardous constituents and corresponding adjusted treatment levels. These adjusted treatment levels would be used for the residual soils (RC-1, EC-1), deferred unit soils (RC-2, EC-1), and the soils excavated for use as fill from PORTS existing landfills (RC-3, EC-1) and selected groundwater contamination areas (RC-2, EC-1). The decisions resulting from Ohio EPA approval of these Ohio Consent Decree documents would be used in other relevant DFF&O post-ROD design documents developed to support excavation or disposal of residual soils generated under the DFF&O.

Only the substantive requirements of the ARARs/TBCs would apply to that portion of the activities conducted entirely on Site under this alternative. All wastes transferred off Site or transported in commerce along public rights-of-way must meet all applicable federal and state requirements. These requirements include packaging, labeling, marking, manifesting, and placarding for hazardous materials in accordance with 49 *CFR* 170-180 *et seq*.

While Alternative 2 has been conceptualized to be in compliance with all action-specific ARARs, there are several location-specific ARARs that only apply if a potential OSDC is built. These location-specific ARARs are associated with siting a potential OSDC. Compliance with these ARARs is discussed in Section 9, where the alternatives are evaluated, but consideration of these ARARs was necessary when developing Alternative 2. Pursuant to the RI/FS SOW of the DFF&O, "if an OSDC is evaluated as a possible remedial alternative under the Site-wide Waste Disposition Evaluation Project, Respondent shall evaluate at least one alternative or sub-alternative that is fully ARARs compliant, with no ARARs waived." DOE evaluated four locations for constructing a potential OSDC (Appendix D). Complying with siting ARARs was a significant consideration in the siting study. Study Area D is the best balance of protective geology and minimal impact to sensitive resources and has been retained as the representative process option location for Alternative 2.

As explained in more detail in the compliance with ARARs evaluation criteria for Alternative 2, there was no room to place a potential OSDC in Study Area D with a volume of 5 million cy and not trigger a need for a waiver. The presence of a nearby stream means that a waiver is needed where it is currently located, but moving the cell would invoke the need to waive other requirements of *OAC* 3745-27-07. The only option left for a potential OSDC at Study Area D to be completely ARAR compliant, requiring no waivers, would be to shrink the size of the cell to just over 1 million cy. Use of just two or three currently designed cells (cells 2, 3, and maybe 6) may allow compliance with all ARARs, but the cell size would be such that only 200,000 to 400,000 cy of waste could be disposed, assuming a 2 to 1 EC-1/EC-2 ratio. The rest would need to be sent off Site, making Alternative 2 roughly the same cost as Alternative 3.

There were no other locations identified that had suitable available land and geology that could meet all ARARs for a 5 million cy cell. Study Areas A and B would require a waiver from federal TSCA requirements to have a separation of 50 ft from the uppermost aquifer to the bottom of the waste to construct an OSDC with a capacity of 5 million cy. Alternatively, 6 million cy of compactable fill at $150 million dollars would need to be used to artificially raise the base of the disposed waste an additional 20 to 30 ft to be above the 50-ft aquifer separation requirements. (This effort would be required at any location at PORTS where the water table is close to the ground surface.) However, even with the compactable fill addition to meet the aquifer separation requirement, Study Area B would continue to require a waiver from the *OAC* 3745-27-07 requirement that the waste not be within 200 ft from a wetland. The unconsolidated sand and gravel geology under both Study Areas A and B is more permeable and therefore much less suitable for waste disposal compared to the bedrock locations (Study Areas C and D), resulting in the need for a much more restrictive WAC to be protective. With a more restrictive WAC, considerably more waste would need to be sent off Site for disposal. Study Area C would require a waiver from the *OAC* 3745-27-07 requirement that the waste not be within 1,000 ft of a residence whose owner has not consented in writing to its location. Study Area C also had a limited capacity that would be allowed for the disposal of PCB waste because of the small area that is 50 ft above the uppermost aquifer. Construction at Study Area C would therefore require a major change in the operation of D&D to segregate PCB waste for off-Site disposal from other on-Site eligible waste.

An alternative (or sub-alternative) of a 5 million cy cell could not be developed at Study Area B, C, or D without some type of a waiver. An alternative that met all waivers could have been developed at Study Areas B, C, and D, but only if the cell had a fraction of the existing capacity, meaning most of the waste would need to be disposed off Site. The only way a large cell could be developed at Study Area A without a waiver would be to bring in millions of cy of compactable fill to raise the bottom of the waste 50 ft above the water table and to accept a much more restrictive WAC. These alternatives provide no advantage over Alternative 3 and are cost-prohibitive. Alternatives with much smaller on-Site disposal capacity or alternatives relying on millions of cy of excess fill and more restrictive WAC were eliminated from further consideration. Therefore, only one on-Site alternative was evaluated, one with a 5-million cy cell placed at Study Area D, which would require one ARAR waiver. In the event that additional waivers are deemed necessary after the ROD is issued, a modification to the ROD would be required. DOE is not aware of the need for any additional waivers at this time.

8.2.3 Alternative 3

The off-Site disposal alternative consists of shipping and disposing of all anticipated D&D waste (RC-1) at appropriately licensed and permitted off-Site disposal facilities or recycling and/or reuse. Waste may be treated at a centralized treatment facility, would be packaged in appropriate containers, and would be shipped either by rail or truck, as appropriate.

Those portions of Alternative 3 conducted on Site would be required to meet the substantive requirements of the ARARs/TBCs identified in Appendix F. Those portions of Alternative 3 conducted off Site would be required to comply with all applicable federal, state, and local requirements. These applicable requirements would include packaging, labeling, marking, manifesting, and placarding for hazardous materials in accordance with 49 *CFR* 170-180 *et seq.*

In addition, CERCLA Section 121(d)(3) provides that any hazardous substance, pollutant, or contaminant generated during response actions and transferred off Site must be sent to a treatment, storage, or disposal facility that complies with applicable federal and state laws and has been approved by EPA for acceptance of CERCLA waste (see also the "Off-Site Rule" at 40 *CFR* 300.440 *et seq.*). Accordingly, DOE would verify with the appropriate EPA regional contact that any off-Site facility meets the aforementioned requirements before transfer.

8.3 DETAILED DESCRIPTION OF ALTERNATIVES

This section provides detailed descriptions of the no-action alternative and on- and off-Site disposal alternatives for the waste streams identified in Section 4. For the sole purpose of supporting a detailed comparative analysis of the alternatives, a conceptual implementation approach has been developed for each action alternative and presented in Section 8.3. The conceptual implementation approach includes a number of assumptions, including the size and configuration of a potential OSDC, to support the detailed analysis of alternatives.

For the action alternatives, costs associated with the D&D of facilities; removal of waste during cleanup actions; waste characterization and certification; waste segregation; treatment as necessary to meet on- or off-Site disposal facility WAC; and waste packaging for on- or off-Site disposal are not included in the estimates.

DOE is committed to the recycling and/or reuse of materials generated through the D&D of the GDP facilities, irrespective of which remedial action alternative is selected. A commitment to recycling and/or reuse is therefore a component of the description of each of the remedial action alternatives. DOE would evaluate the individual material and regulatory waste types throughout the implementation of the D&D process, and recycle and/or reuse materials as appropriate. For purposes of evaluating remedial action alternatives, this RI/FS assumes that the same amount of materials would be recycled under both action alternatives and therefore it is not a discriminating factor in the comparative analysis presented in Section 9.3. On this basis, a consistent set of assumptions has been made in regard to the recycle and/or reuse of materials and included in both of the two action-based remedial alternatives.

8.3.1 Description of Alternative 1

The no-action alternative is considered in accordance with DFF&O and NEPA requirements to provide a baseline for comparison with other alternatives. No institutional controls, no demolition, and no waste disposal occur under this alternative. There are no components or elements to describe.

8.3.2 Description of Alternative 2

The following GRAs and process options that were identified as representative process options in Section 7 have been used to describe Alternative 2:

- Institutional Controls on a potential OSDC
  - Physical barriers/security
  - Covenants and deed restrictions
  - S&M
  - Environmental monitoring.

- Centralized Treatment
  - Size and void reduction
  - Decontamination
  - New treatment plant (for secondary wastewater treatment).

- On-Site Disposal
    - Engineered disposal cell (for new on-Site disposal facilities)
    - On-PORTS fill.

- Off-Site Disposal
    - DOE off-Site facility
    - Permitted commercial facilities.

- Recycle and/or Reuse

- Waste Transportation
    - Truck
    - Train.

Alternative 2 includes the consolidated disposal of generated D&D waste (RC-1) in a newly constructed, engineered waste disposal facility (a potential OSDC) at PORTS. Candidate wastes would include construction and demolition debris, solid waste, LLW, RCRA waste, TSCA waste, and mixed wastes consisting of combinations of these regulatory waste types that meet the facility's WAC, which are presented in Section 7.5. Wastes not meeting potential OSDC WAC would be transported to off-Site disposal facilities or, if feasible, treated to attain the WAC for the on-Site or off-Site disposal facility. Additionally, under Alternative 2, a volume of D&D-generated material would be recycled and/or reused. Liquid wastes, TRU wastes, and high-level waste or spent nuclear fuel are not considered to be candidate waste streams for a potential OSDC.

8.3.2.1 D&D waste (RC-1) volume

The design capacity of the cell is based on the waste generation volumes established in Section 4.1. D&D waste volumes (RC-1, EC-1 and EC-2) that were used to calculate the volume and are used throughout this discussion are shown in Table 8.1. Also shown are the appropriate fill volumes needed and additional waste (EC-2) and fill volumes that result from selecting contaminated areas as the source of fill (RC-2, RC-3). The waste forms are described in a manner that supports handling decisions at a disposal facility. Soil (EC-1) is packaged and disposed differently from non-soil waste (EC-2). These waste form descriptions are used throughout this section to describe how waste is handled at a potential OSDC. The volumes in the table are in situ volumes. The waste volume capacity of a potential OSDC accounts for fill volumes used for proper disposal of waste with void spaces and for daily cover. The conceptual design capacity is also based on maximizing the efficiency of land use by considering topographic and hydrogeologic features of the disposal location.

Table 8.1. Waste Disposition Volumes Used to Determine Cell Capacity

D&D Waste (RC-1) Forms and OSDC Fill (RC-2, RC-3) Description	In Situ Volume (cy)	Disposed Volume in OSDC in Alternative 2 (cy)	Disposed Off Site in Alternative 2 (cy)
Residual Soil (RC-1, EC-1)	53,000	53,000	0
Asbestos, concrete, and other building waste (RC-1, EC-2)	1,032,000	966,000	66,000
PGE (RC-1, EC-2)	272,000	112,000[a] (in situ 219,000)	41,000[a] (in situ 53,000)
Targeted Recyclables	110,000	0	110,000
Total D&D Waste (RC-1) and Recyclables	**1,467,000**	**1,131,000**	**217,000**
Non-D&D Landfill waste requiring fill (as a result of using area as OSDC fill source-RC-3, EC-2)	227,000	223,000	4,000
Total D&D and Fill Waste (RC-1, RC-3, EC-2)	**NA**	**1,301,000** (does not include 53,000 cy of D&D residual soil)	**221,000**
OSDC Fill[b] (RC-1, RC-2, RC-3, EC-1) required to achieve 2:1 ratio	NA	2,602,000	NA
Total OSDC minimum capacity	NA	3,903,000	NA

[a] Much of the PGE is segmented, resulting in a volume reduction for disposal.
[b] Assumed fill sources include landfills inside Perimeter Road (RC-3), contaminated soil from contaminated groundwater plumes (RC-2), and contaminated soil from RCRA deferred SWMUs (RC-2). Additional authority is required to excavate and dispose of these assumed fill sources.

D&D = decontamination and decommissioning
EC = engineering category
NA = not applicable
OSDC = on-Site disposal cell
PGE = process gas equipment
RC = regulatory category
RCRA = Resource Conservation and Recovery Act of 1976, as amended
SWMU = solid waste management unit

Table 8.2 presents the regulatory waste types along with the disposal location for waste generated under the DFF&O (RC-1). These volumes do not include the 110,000 cy of recycled material. These waste types are used to determine where a waste can be disposed and whether or not treatment is required to meet the WAC. Additionally, it was assumed that all hazardous waste that is generated from the D&D of buildings (except residual soil-RC-1, EC-1) would be taken off Site and any treatment required to meet LDRs would occur at the off-Site facility. However, the LLW/TSCA chemical waste and other waste taken off Site is a representative volume of waste that is either generated before a potential OSDC is operational or might exceed the WAC at a potential OSDC.

Table 8.2. Regulatory Type of D&D Waste (RC-1) Disposed, Alternative 2

Type of D&D Waste (RC-1) Disposed	Estimated On-Site Volume[a] (cy)	Estimated Off-Site Volume[a] (cy)
RCRA Hazardous-CAMU ineligible	0	400
RCRA Hazardous-CAMU eligible	53,000	0
TSCA	0	0
C&DD	17,500	14,500
Solid	6,700	3,500
LLW/RCRA Hazardous-CAMU ineligible	0	100

Table 8.2. Regulatory Type of D&D Waste (RC-1) Disposed, Alternative 2 (Continued)

Type of D&D Waste (RC-1) Disposed	Estimated On-Site Volume[a] (cy)	Estimated Off-Site Volume[a] (cy)
LLW/RCRA Hazardous-CAMU eligible	0	0
LLW/TSCA	33,000	4,000
LLW/C&DD	765,500	21,300
LLW/Solid	363,000	74,500

[a] Volume assumptions regarding CAMU-eligible and CAMU-ineligible wastes were made for the purpose of evaluating alternatives. DOE has not proposed a CAMU yet and, therefore, no determinations have been made regarding what waste is or is not CAMU eligible. DOE may need to revise these estimates in the future.

C&DD = construction and demolition debris
CAMU = Corrective Action Management Unit
D&D = decontamination and decommissioning
DOE = U.S. Department of Energy
LLW = low-level (radioactive) waste
RC = regulatory category
RCRA = Resource Conservation and Recovery Act of 1976, as amended
TSCA = Toxic Substances Control Act of 1976

Only two of the assumptions used in determining on and off-Site volumes would be commitments if Alternative 2 is selected. The first is that converters and compressors from X-326 would be sent off Site for disposal. The second is that any waste that exceeds the WAC prior to disposal would be sent off Site for disposal.

The major elements of Alternative 2 are the following:

- A potential OSDC design (Section 8.3.2.1.1)
- Pre-design studies (Section 8.3.2.1.2)
- Site preparation and potential OSDC construction (Section 8.3.2.1.3)
- WAC (Section 8.3.2.1.4)
- Potential OSDC operations (centralized treatment, staging, waste disposal, and wastewater collection and treatment) (Section 8.3.2.1.5)
- Fill operations (Section 8.3.2.1.6)
- Potential OSDC capping and support facility dismantlement (Section 8.3.2.1.7)
- Post-operations S&M (Section 8.3.2.1.8)
- Off-Site disposal (Section 8.3.2.1.9)
- Recycling and/or reuse (Section 8.3.2.1.10).

8.3.2.1.1 Potential OSDC design

A potential OSDC would consist of an engineered disposal cell that meets the requirements of ARARs/TBCs in Appendix F, including requirements related to disposal of RCRA hazardous wastes, TSCA wastes, and LLW. A potential OSDC design would include sufficient capacity to accept the anticipated waste to be generated from the D&D of PORTS (RC-1). The design basis for a potential OSDC attains all ARARs/TBCs and incorporates the following:

- Effective protection of human health and the environment through waste isolation for 1,000 years

- Protection against animal and plant intrusion, and minimization of the potential for human intrusion

- Reduction of potential for incremental and total settlement, and slope failure under static and seismic conditions through proper design and waste placement techniques.

A potential OSDC design is the result of an iterative process involving development and review of the cell design in conjunction with evaluation of the candidate waste streams and facility WAC development, which results in a facility that meets the performance objectives established in DOE Order 435.1. This process involves demonstrating that a cell design is protective of a hypothetical receptor. Three elements of disposal facility design are critical to ensuring adequate long-term protection of human health and the environment: (1) design of the cell's waste containment features, (2) location of the cell, and (3) characteristics of the waste placed in the disposal cell.

The major components of this design include the multi-layer base liner, the permanent cap, leachate collection and treatment system, and support facilities. Appendix J contains the plan view drawings and cross sections for the conceptual design for a potential OSDC that are used solely to support an evaluation of the alternatives.

Multi-layer Base Liner System

The purpose of this system is to prevent leachate from migrating out of the disposal unit. A compacted clay liner with a double geocomposite liner system is proposed, along with two low-permeability liners, a leachate collection and removal system, and a leak detection system. The top (primary) liner would be "constructed of materials (e.g., a geomembrane) to prevent the migration of hazardous constituents into the secondary liner for the active life and post-closure care period." The lower (secondary) component of the composite bottom liner would be designed and constructed using materials to minimize the migration of hazardous constituents if a breach in the compacted clay liner were to occur. The leachate collection system would be designed, assembled, and installed to be fully functional while the leak detection system would be capable of detecting leachate movement through the primary liner in excess of the action leakage rate. The base liner proposed for the conceptual design includes the following layers, from the cell base up:

- <u>Compacted clay liner</u>: A 3-ft-thick, low-permeability clay layer would be placed above the cut elevation (stable soil or bedrock) and have a hydraulic conductivity $\leq 1\times10^{-7}$ cm/s.

- <u>Secondary liner</u>: A geosynthetic clay liner (GCL) and flexible membrane liner (FML) would be installed. The FML would be a man-made geosynthetic barrier composed of materials compatible with the waste and resistant to degradation by the chemical constituents expected to be present in the leachate. A typical GCL consists of sodium bentonite encapsulated between two geotextiles. The GCL, which is less than 1 in. thick, typically has a hydraulic conductivity on the order of 5×10^{-9} cm/s.

- <u>Leak detection system drainage layer</u>: This is a 1-ft gravel leak detection layer sandwiched between two geotextile layers on the cell floor. This layer would be graded to drain toward detection piping. At each location where the leak detection piping penetrates a layer of the primary and secondary liner, an antiseep collar would be installed to prevent development of a preferential flow pathway. The detection piping would be connected to a separate detection sump in the leachate collection and transfer facility downgradient of the disposal cell. Little or no leachate is expected to be captured by this system during the operations or post-operations period.

- Primary liner: The primary liner would retard leachate migration out of the disposal cell and direct leachate into the primary leachate collection layer. The conceptual design includes an FML and a low-permeability GCL.

- Leachate collection system drainage layer: The primary leachate collection system drainage layer consists of a 1-ft-thick gravel layer on top of the primary liner. The leachate collection system drainage layer is sandwiched between two layers of geotextile on the cell floor and would collect significant volumes of leachate draining through the waste mass during operations and before placement of the cap, and small volumes of leachate during the post-operations period. The geotextile layers would cushion and protect the primary liner and retard infiltration of fines from the overlying soil and waste into the gravel, which would prolong the functional life of the leachate recovery system. Perforated leachate collection pipes would be placed at the base in the gravel drainage layer and collect leachate in a central line that gravity flows out of the cell to a collection sump in the leachate collection and transfer facility. The primary leachate collection system would be designed with perforated collection piping and antiseep collars similar to those in the leak detection system drainage layer. Man-made materials would be selected for compatibility with the expected leachate chemistry.

- One-ft protective soil layer: A protective soil layer at least 1 ft thick would be placed over the upper leachate collection system geotextile to prevent damage to the underlying layers during operations.

Figure 8.1 shows a typical cross section of a potential hazardous waste landfill liner system with the various layers that form a portion of the waste containment system.

The final cover would be designed and constructed to do the following:

- Minimize migration of liquids into the closed disposal cell over the long term

- Promote drainage and minimize erosion or abrasion of the cover

- Accommodate settling and subsidence to maintain the cover’s integrity

- Provide a permeability less than or equal to the permeability of any bottom-liner system or natural subsoils present

- Resist intrusion of humans, plants, and animals

- Minimize future maintenance.

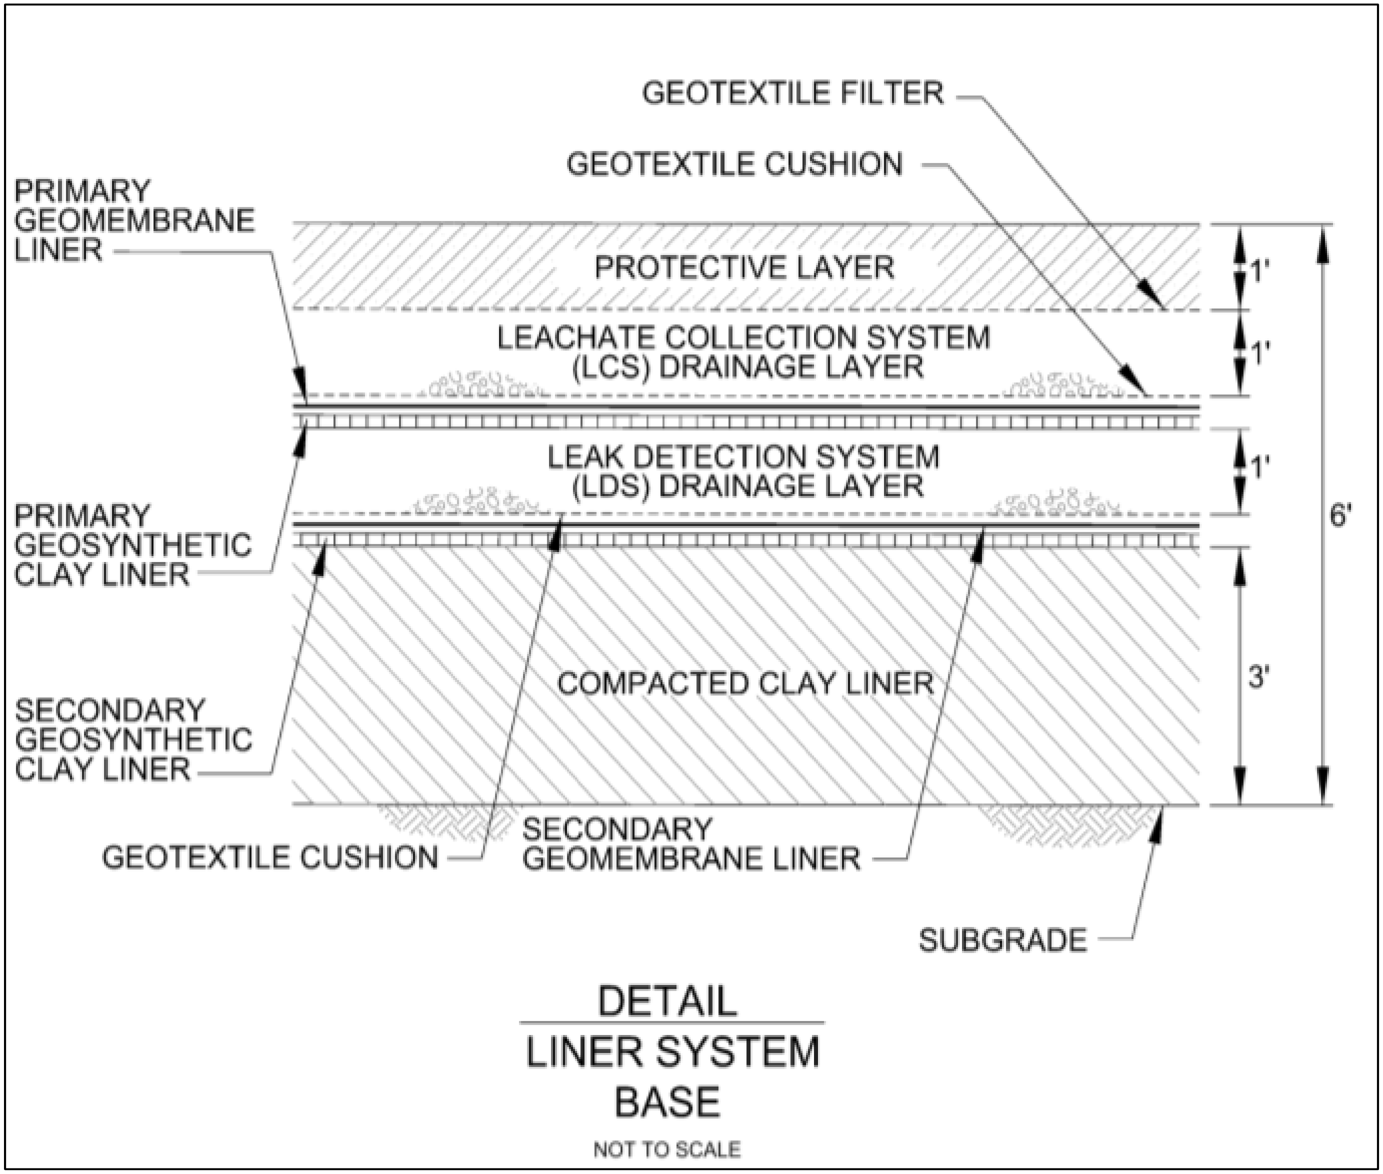

Figure 8.1. Typical Section View – Landfill Base Liner System Details for Alternative 2

Final Cover System

The cover would be sloped to facilitate runoff and would be placed over the waste and into the perimeter of the disposal cells. The conceptual design developed for alternative evaluation for the nominal 10-ft-thick cover consists of the following elements, from the top of the waste to the top of the cap:

- Soil contour layer: Following the placement of waste to final grade in any area, a soil contour layer would be placed over the waste to reduce infiltration and contain the waste before capping. The soil contour layer would include a 1-ft minimum clay contour soil layer to provide an intermediate uniform layer between the wastes and the final cover. This cover would bring the disposal cell to final grade in preparation for cover placement, reduce infiltration, and protect the permanent cover layer from settlement within the waste cell. With proper maintenance of the soil contour layer, this temporary cover would reduce infiltration sufficiently, pending installation of the other cap components.

- Secondary hydraulic barrier: During final capping, a 2-ft-thick, low-permeability clay layer would be placed above the soil contour layer. This layer is considered to be the secondary hydraulic barrier and would be similar in design to the low-permeability clay layer of the secondary base liner.

- Primary hydraulic barrier: A GCL and FML would be installed above the low-permeability soil layer. The GCL would serve as an additional low-permeability layer and would prevent infiltration. A thin geotextile cushion would be placed above the GCL.

- Drainage layer: Above the FML would be a 1-ft gravel drainage layer sandwiched between two layers of geotextile. The upper geotextile would minimize clogging of the drainage layer, and the lower geotextile would protect the FML from puncture.

- Biointrusion barrier: A 3-ft biointrusion barrier would prevent burrowing animals and plant root systems from penetrating the cover system and would also discourage inadvertent human intrusion by increasing the difficulty of digging or drilling into the cell. This layer would be constructed of cobbles (large, rounded stones) and would facilitate infiltration of water into the drainage layer. A 6-in., graded, natural filter (a granular layer) sandwiched between two layers of geotextile would overlie the biointrusion layer to prevent clogging of the porous layer with overlying soil.

- Vegetative soil layer: A 2-ft vegetated soil layer over the filter layer (at a 2 to 2.5 percent grade on top of the cap) would provide conditions that support a vegetative cover to reduce erosion. A 6-in.-thick layer of topsoil would provide for permanent vegetation on top of the cap. To eliminate erosion until the permanent vegetation is established, an erosion mat would be installed to protect the other cover layers from the effects of wind and water erosion. This layer would accommodate the typical root systems of planted and native vegetation. This layer, the drainage layer, and the biointrusion layer together would be much thicker than the local frost depth, preventing frost damage to the FML and the low-permeability soil layer.

Figure 8.2 shows a typical cross section of a potential hazardous waste landfill cover system with the various layers that form a portion of the waste containment system.

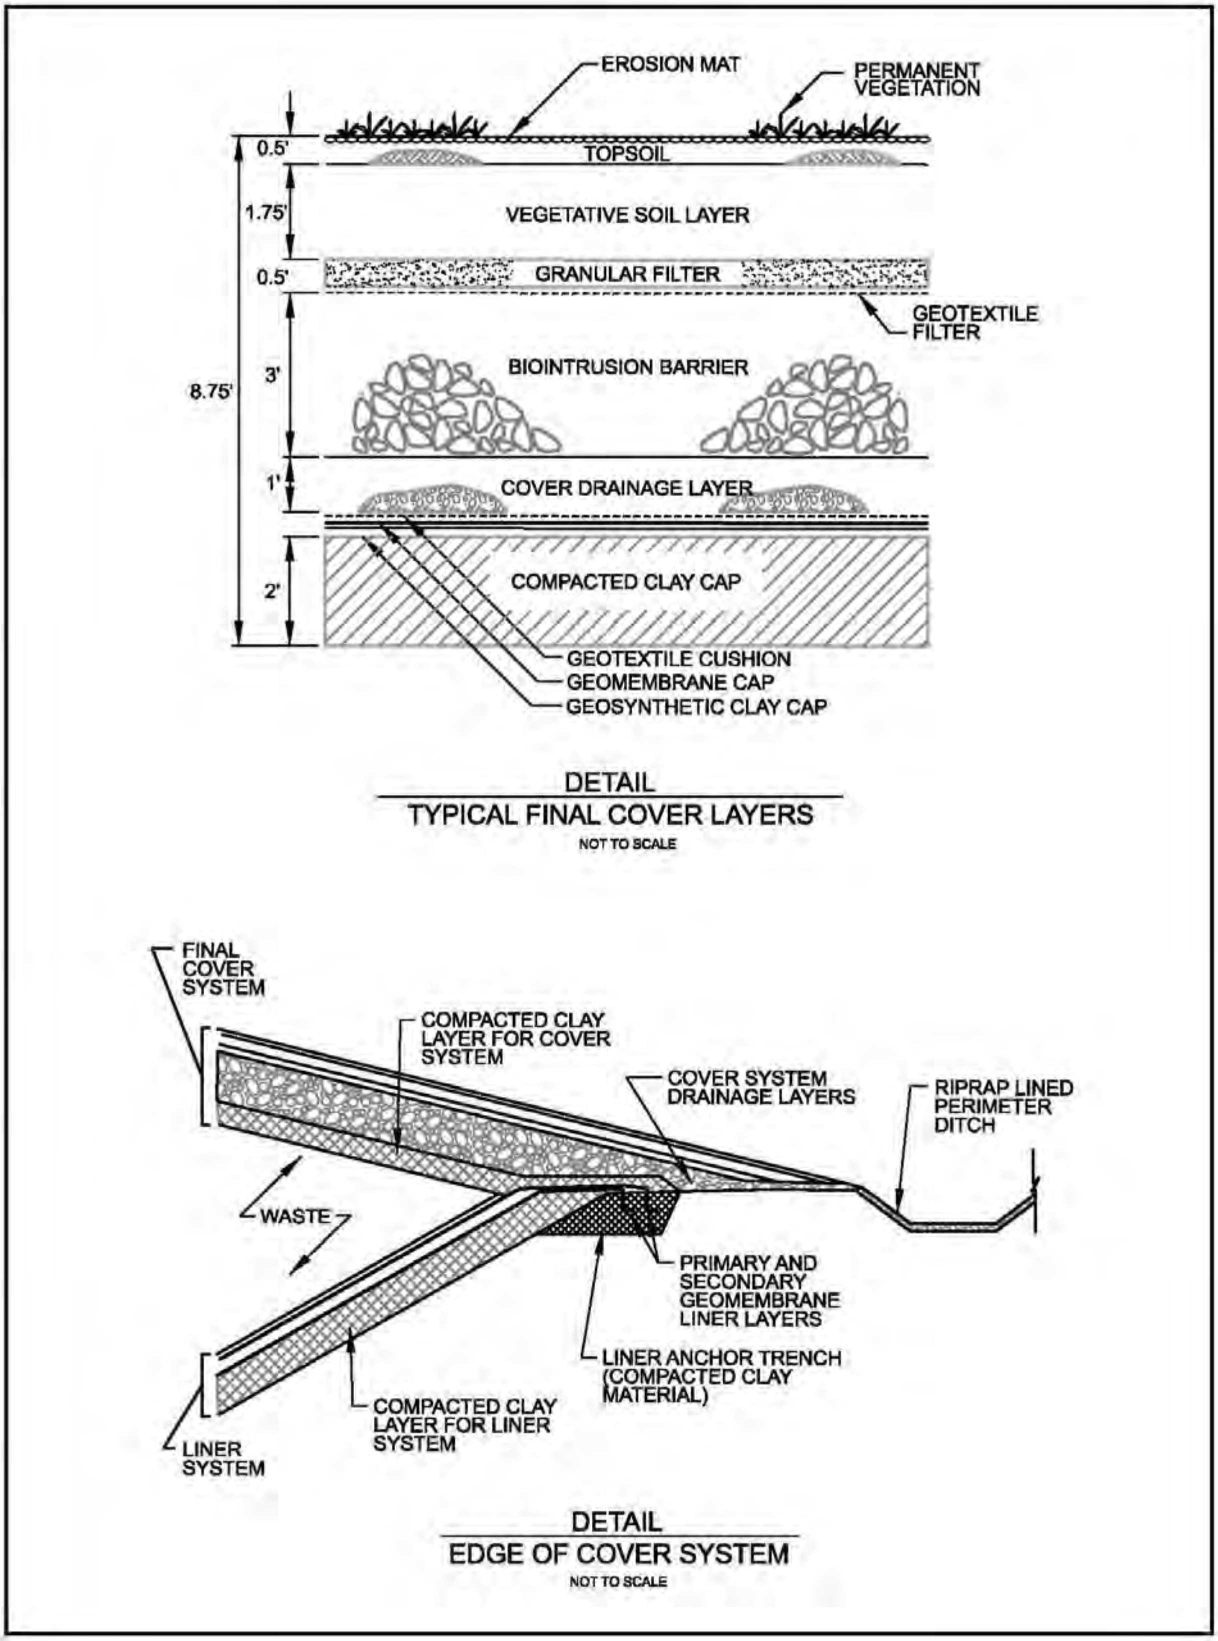

Figure 8.2. Typical Section View – Landfill Final Cover System for Alternative 2

Water Collection Systems and Leachate Treatment Systems

The leachate collection system and leak detection system drainage layers located in the base-liner would gravity drain to a sump/vault system located just outside each waste cell. Each sump/vault would have valve piping controls to control gravity leachate flow to an on-Site leachate lift station pump system.

Liquid-sensing detection equipment in the sump/vault connected to the secondary leak detection system would provide monitoring of the action leakage rate, which is an indicator of whether the primary liner is intact and not leaking in excess of the action leakage rate (to be set during design). Liquid detectors connected to the leachate collection and leak detection systems would monitor collected leachate levels. Valve controls would allow leachate to be released by gravity, drain to the lift station pump system, and be pumped to the interim leachate treatment system (in operation during waste disposal).

Nonimpacted storm water draining from construction access roads and other nonwaste handling facilities would drain along drainage swales, enter surface water conveyance ditches, enter sedimentation ponds, and ultimately be released to surface water bodies. Impacted storm water (water potentially impacted as a result of waste handling activities, called contact water) from the waste haul road and inside the disposal cells would gravity flow or be pumped into a series of modular tanks strategically placed to take advantage of the existing topography. These tanks would temporarily hold the storm water to allow suspended particulates to settle. After settling, temporary pumps and lines would be used to pump water from these facilities to the interim leachate treatment system, if treatment is needed. The capacity to treat this water would exist, but alternatively, the water in these tanks could be discharged if sampling and analysis determines it to be acceptable for release.

The interim leachate treatment system assumed for alternative evaluation would include chemical precipitation, ion exchange, and carbon absorption to handle the constituents expected in the wastewater. The interim system would treat contact water and leachate during potential OSDC operations. During potential OSDC capping, the interim system would be replaced by a permanent leachate treatment system consisting of a fixed treatment system sized to handle the expected post-operations leachate generation rate. Leachate would be monitored to confirm effectiveness of each of the collection and treatment systems. Modifications to the system would be made if required to ensure protectiveness.

The permanent leachate treatment system would be designed to treat constituents expected to be in the leachate that would be generated continuously after the post-operations period. This system would be a fixed-in-place, active system with processes similar to those of the interim system. It would operate as long as notable leachate is generated. For the purposes of the FS cost estimate, this operating period is assumed to be 30 years.

As the leachate generation rate stabilizes to an expected low level, the permanent leachate treatment system would be replaced by a passive treatment system. The new system would be designed to passively treat leachate prior to discharging it to surface water by gravity flow. This passive system would be installed during potential OSDC capping. It would only become operational when the permanent leachate treatment system is dismantled, and the leachate conveyance system is altered to direct leachate through the passive treatment media. The passive treatment system would consist of reactive barrier material in a tank system to which leachate is gravity-fed, allowing sufficient residence time to remove contaminants from the leachate and ultimately release the treated water to a nearby surface water body. Such a system would require little, if any, direct management.

Support Facilities

A support area and an exclusion area would be established within the fenced control area of the on-Site disposal facility. The conceptual design developed to support the alternative evaluation for the support area includes an office area, an employee and visitor parking area, and a guard station at the main gate. An employee facility would connect the exclusion area to the support area and would include personnel showers, restrooms, monitoring and decontamination equipment, and a break area. Water from showers and toilet facilities would go to a collection tank for disposal at a wastewater treatment plant.

Waste operations would be conducted in the exclusion area, which would be assumed to be contaminated during operations. Any personnel, equipment, vehicles, or containers leaving the exclusion area would be monitored and, if necessary, decontaminated. Clothing worn in the exclusion area would be washed or packaged for disposal. An enclosed decontamination facility with a collection sump, pump, and high-pressure water spray equipment would be available to inspect and decontaminate vehicles, equipment, and containers, as necessary. Decontamination water collected in the sump would be pumped to the on-Site interim leachate treatment system and be discharged when discharge limits are met. An equipment storage, maintenance, and fueling area would be constructed in the exclusion area for use during operations.

A waste staging area, called the impacted material transfer area (IMTA), inside the exclusion area would serve as a temporary storage area for incoming waste. This area would be used if the rate of incoming waste deliveries exceeds the rate of waste placement in the disposal facility, as could occur during inclement weather. It would also be used to stockpile waste to allow the most economical placement of waste requiring fill (EC-2) and waste that can be used as fill. The IMTA is assumed to be constructed of the following: 2-ft compacted base followed by a geotextile cushion, 80-mil geomembrane liner, geonet, geotextile fabric, and finally a 1-ft soil protective layer graded to drain. The 7-acre IMTA would be graded so water would flow by gravity to a sump pump system. The collected impacted water would be pumped to the interim leachate treatment system and be discharged when discharge limits are met.

A haul road would be constructed from the OSDC support area adjacent to the IMTA to the North Access Road and eventually to Perimeter Road. An overpass over Fog Road is currently planned. It is anticipated that waste trucks would cross Perimeter Road and use plant roads to access the areas of waste generation. No trucks are anticipated to be on any roads with public access.

Existing groundwater monitoring wells would be used to monitor the quality of the underlying groundwater, where possible. Additional groundwater monitoring wells would be installed as needed. Air monitoring equipment would be installed for use during construction and operations.

8.3.2.1.2 Pre-design studies

Pre-design studies would be implemented to provide data necessary to support the basis of design for a potential OSDC at PORTS. These data are anticipated to be generated from a series of field and laboratory studies focused on the following: (1) physical and chemical characteristics of projected wastes, (2) natural and man-made materials used for facility construction, (3) compatibility of leachate with the man-made materials, (4) subsurface conditions of a location for a potential OSDC, (5) clay liner construction approach, (6) waste placement and compaction approach, and (7) visual impact survey. These studies, implemented under formal SAPs or by project consensus, are intended to establish design parameters and technical specifications that achieve the stated performance requirements for a potential OSDC and establish field construction QC parameters. A summary of potential studies follows.

Physical and Chemical Characteristics of Projected Waste

To understand the chemical characteristics of the waste generated under the D&D of PORTS, both intrusive and nonintrusive samples are being collected for analysis of VOCs, SVOCs, PCBs, metals, and radionuclides, as appropriate. Nonintrusive characterization using NDA is also occurring to validate process knowledge assumptions regarding the distribution of radioactive and chemical (nonradioactive) hazardous constituents held up within the process gas system of the former gaseous diffusion process equipment.

Natural and Man-made Materials Used for Facility Construction

Local sources of natural materials, including clay and rock, would be tested in the laboratory to determine whether the properties of these materials meet the minimum technical guidelines established in federal and state regulations for landfill facility design. A Construction Materials Source Evaluation Work Plan would be developed to provide details of this program. Only those materials meeting the minimum technical guidelines would be used for construction.

Additionally, natural and man-made materials (including geosynthetic clay liners and geomembranes) would be tested for internal and interface shear strength (as appropriate) to evaluate their characteristics and ensure they are appropriate for use in the disposal facility and that the design parameters are appropriate. This testing program is detailed in the Soil/Geosynthetic Direct Shear Testing Program Work Plan.

Compatibility of Leachate with the Man-made Materials

The expected composition of leachate (e.g., chemical makeup, pH) from the disposal facility would be determined. This anticipated composition will then be used to evaluate its compatibility with geomembrane and geosynthetic clay liner materials. Details of these evaluations would be presented in the Geomembrane-Leachate Compatibility Study and the Geosynthetic Clay Liner-Leachate Compatibility Study.

Subsurface Conditions at a Location for a Potential OSDC

Geological and geotechnical data and information related to detailed subsurface conditions of a preferred location for a potential OSDC must be known in order to incorporate these conditions into the overall design of the facility to ensure protectiveness objectives are met. Test pits into the geologic strata were performed. The test pits provided an indication of the effort required to prepare the location for OSDC construction. Additionally, boreholes into the strata provided soil samples and rock core samples on which geotechnical analyses were performed to establish design parameters. Such analyses include, but are not limited to, classification, moisture content, specific gravity, Atterberg limits, standard Proctor, consolidation, California bearing ratio, and shear strength. These parameters support design parameters and project Technical Specifications for measurements, tolerances, and materials of construction of a potential OSDC.

Clay Liner Construction Approach

A Clay Liner/Cap Test Pad Work Plan was developed and the program has been initiated. Preconstruction samples were collected and sent to the laboratory for analyses. A 3-ft-thick clay liner test pad was constructed using construction equipment and techniques expected to be used during construction of an OSDC. Sealed double-ring infiltrometer tests were performed on two lanes of the test pad. The sealed double-ring infiltrometers have been decommissioned and samples were collected and sent to the laboratory for testing. Laboratory testing of these final samples is ongoing.

Waste Placement and Compaction Approach

Waste placement in a potential OSDC would be performed in a manner such that the waste material would be placed in a soil matrix. This soil matrix is expected to consist primarily of Minford soil. In order to identify potential issues related to placement, testing, or verification of this soil, a test strip of Minford soil was constructed in conjunction with the test pad construction activity. The test strip consisted of placement of a 1-ft-thick lift of soil and then compacting it with various pieces of construction equipment. The results of the test strip would support development of the Impacted Material Placement Plan which provides the waste placement and construction quality control requirements.

Visual Impact Survey

A visual impact survey is underway. The survey illustrates a potential OSDC's resultant visual impact on the surrounding community. Using GIS technology and the proposed height of a potential OSDC, the survey is identifying locations in the surrounding community where the potential OSDC may be visible. Results, when available, would be included in subsequent documents.

8.3.2.1.3 Site preparation and potential OSDC construction

Construction activities for a potential OSDC would include site development, disposal cell base liner construction, construction of support facilities, and capping.

Site development actions would be performed to minimize environmental impacts, as required in the ARARs for site preparation included in Appendix F. Site clearing and grubbing would occur to remove trees and other vegetation to provide sufficient open area for construction. To the extent practical, most clearing would occur during autumn or winter to protect the nests of migratory birds and bats during breeding season. Avoiding clearing during the months of April through September, to the extent practical, would protect against potential impacts to the Indiana bat. (Although Indiana bats have never been found at PORTS, Indiana bat habitat is present at the disposal location.) The footprint for the disposal cell would be prepared, including removal of bedrock (if present), to provide a below-grade bedrock base for the facility and similar side slopes for lateral containment. The material removed from the location is assumed to be stockpiled for cost estimating purposes. One potential location is the X-611B Sludge Lagoon to fill in the lagoon.

Existing gravel roads would be upgraded. New gravel roads would be constructed for the disposal facility (as required). A temporary haul road from the D&D area and access roads for the support facilities would be constructed, and the IMTA would be developed. Detention basins, runoff control ditches, and placement of support facilities, as well as the cell itself, would be considered to prevent run-on and protect streams from construction activities.

Water, electricity, telephone lines, and sanitary waste facilities (septic system or collection tanks) would be established on Site. Temporary fences and gates would be installed to restrict the controlled area of the operation. Additionally, temporary office and change facilities, as well as storage buildings, would be installed as required.

When site preparation activities are complete, construction of the cell would begin. The disposal cell would be constructed in phases consistent with waste generation schedules. In general, it is assumed that only two cells would be constructed at a time. Once operational, construction would begin on the next two cells. When the initial cells are filled and the side slopes are sufficiently stable, a portion of the final cap would be installed with a geosynthetic liner extending out enough to allow for seaming with the adjacent liner. This sequence would continue until the requisite capacity is achieved. Figure 8.3 shows the scheduled sequence of design, construction, operations, and capping actions.

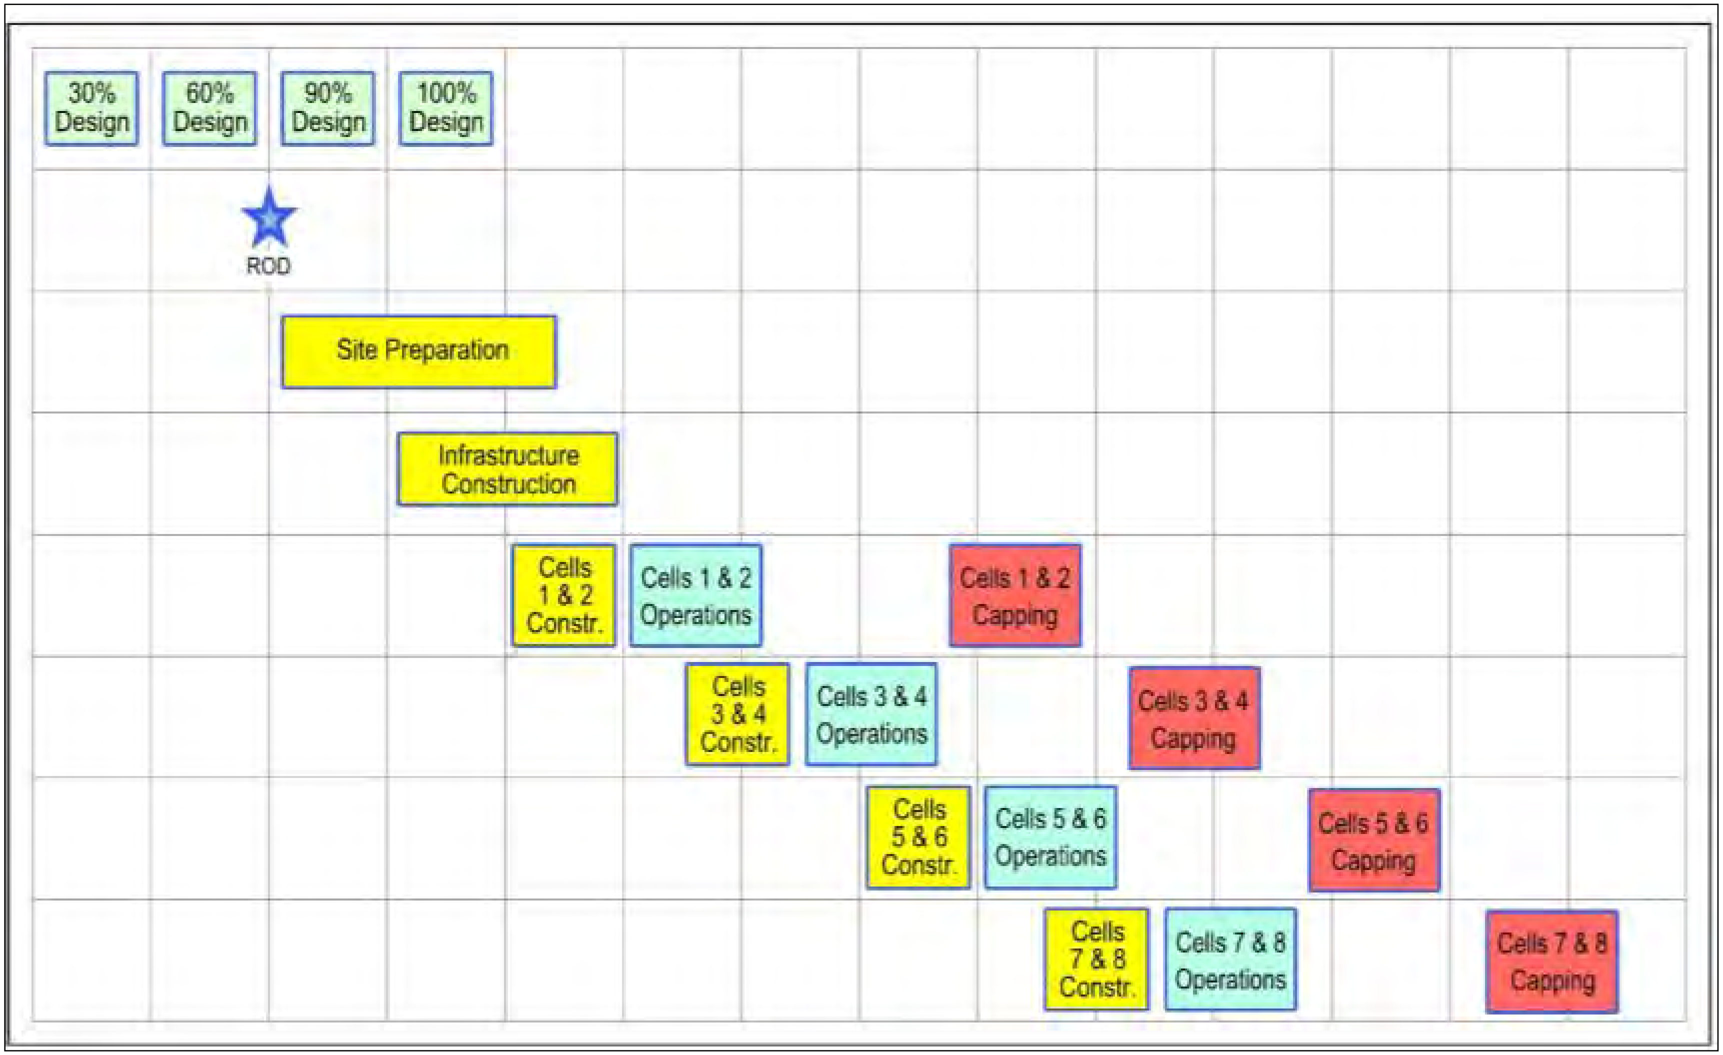

Figure 8.3. Construction/Operation Sequence for a Potential OSDC at PORTS

Initially, materials required for potential OSDC construction would be mobilized. This would include a large volume of clay-rich soil (low permeability clay) from a borrow area in the vicinity of the area for construction of the 3-ft-thick clay liner. Potential locations for obtaining borrow material were evaluated in Pike County and neighboring counties. Testing of clay soil material from off-PORTS borrow areas would be required during subsequent design phases. Excess clay from development of the municipal landfill in Pike County is currently available and could be a suitable choice for use at PORTS if it is available at the time of construction. If needed, this material would likely be processed at the construction location in a soil pug mill to remove rocks, resulting in a uniform and consistent clay soil. The clay would be installed in accordance with the requirements established using a test pad in order to achieve the requisite layer hydraulic conductivity.

Following installation of the clay liner, the other layers of the base liner would be installed. This would include, from bottom up, the primary high density polyethylene (HDPE) liner, leak detection system, secondary HDPE liner, leachate collection system (including a porous granular layer on the cell bottom), and protective soil layer. The leachate collection system, being a gravity flow system, would exit through the cells and connect to a leachate header. The header would convey leachate to the interim leachate treatment system.

Appropriate construction practices would be used in all excavation and construction areas, including the borrow area, to control surface water runoff and minimize erosion and transport of sediment from exposed areas. These measures would include constructing berms to direct the flow of surface water; constructing silt fences to minimize the amount of sediment leaving the area; covering the exposed area with straw, mulch, riprap, or membranes; and using revegetation mats in those areas with high water velocity. Sediment detention basins constructed near the perimeter of the construction area would protect against transport of sediment. Runoff from contaminated areas would be segregated from clean runoff and be collected and treated as necessary.

Based on the location and geological subsurface, it is estimated that roughly 5 million cy of capacity is available for waste plus fill at the representative location, Site D. The current volume estimates for D&D waste (RC-1, EC-2) and associated required fill (RC-2, RC-3, EC-1), plus the additional volume needed for waste requiring fill (RC-3, EC-2) that may be generated when removing fill from contaminated borrow locations, suggest that 3.9 million cy of space is needed in any potential OSDC. This volume assumes 1.08 million cy of D&D waste requiring fill (RC-1, EC-2) is disposed at a potential OSDC from D&D of the GDP plus another 223,000 cy of landfill waste also requiring fill (RC-3, EC-2) that is estimated to be generated in the process of removing materials for fill. Therefore, the total fill requirements are 2.6 million cy, and the total potential OSDC volume needed is 3.9 million cy. The estimate of required fill volume, as stated above, is reduced by 53,000 cy because of the residual soil (RC-1, EC-1) anticipated to be generated during the demolition of slabs and subsurface structures under the Process Buildings and Complex Facilities D&D Evaluation Project. A cell layout of 5 million cy is considered for the purpose of the analysis of alternatives in this RI/FS to account for waste from other actions that might be performed in the future and to ensure sufficient capacity is available if actual waste volumes or required EC-1/EC-2 ratios increase. Figure 8.4 presents a conceptual design layout of a potential OSDC sized for 5 million cy. As shown in the cross sections included in Appendix J, the entire footprint of the cell is located on competent bedrock (Cuyahoga shale). Also included on Figure 8.4 is the conceptualized location of the haul road to bring waste to a potential OSDC from the demolition areas. Most of the new road will be constructed in disturbed areas with a large portion using an upgraded North Access Road.

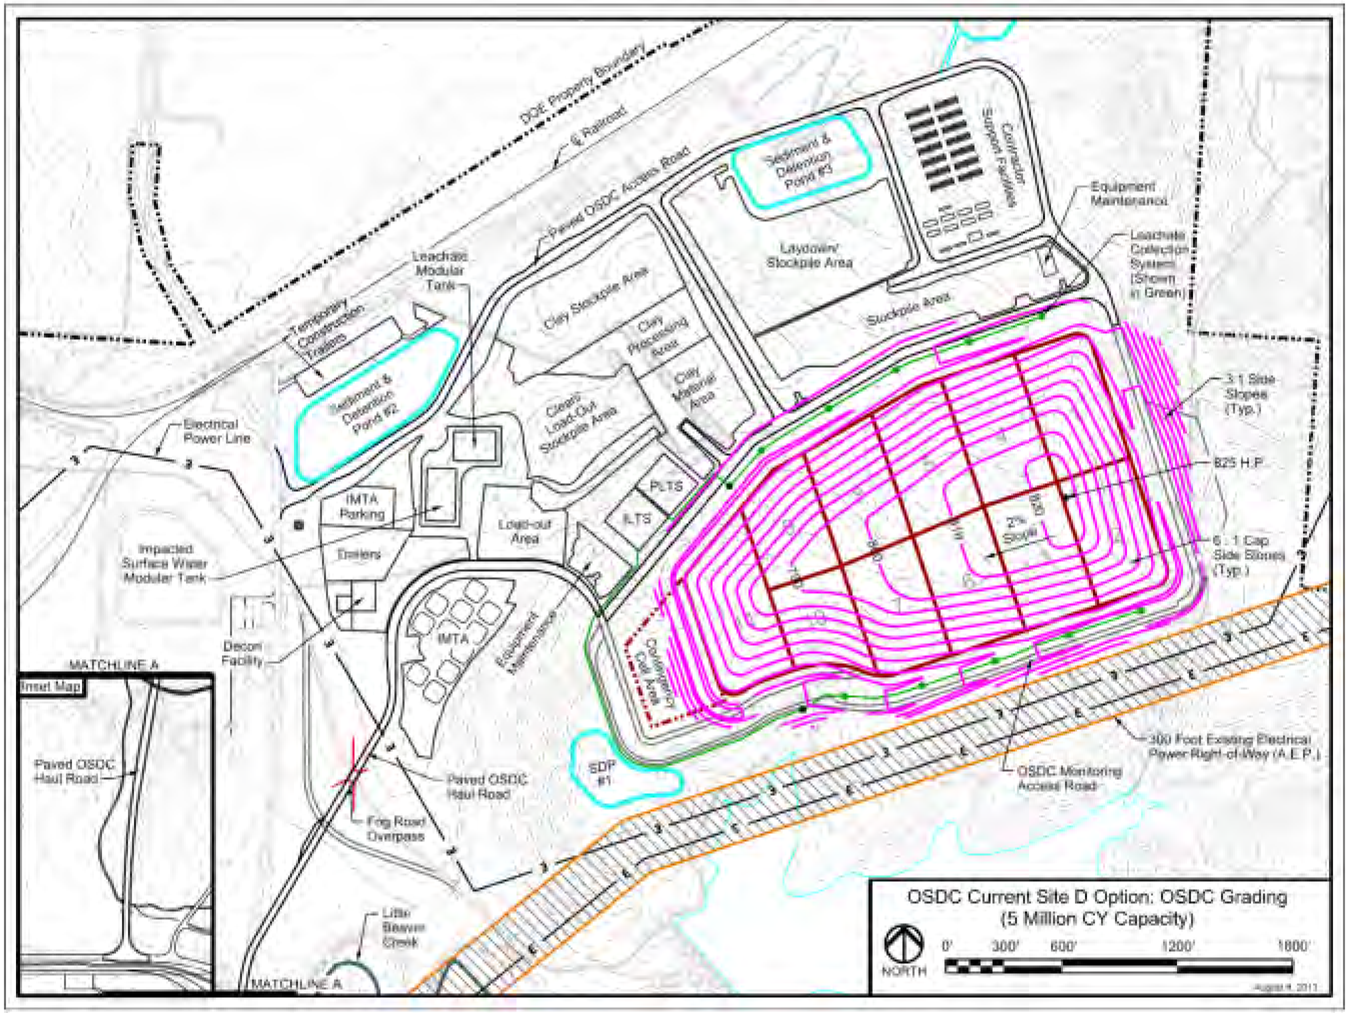

Figure 8.4. Landfill Plan View – Finished Grading Plan for Alternative 2

The cell operations for Alternative 2 would occupy approximately 320 acres, which would include a potential OSDC as well as the required support facilities such as the IMTA, leachate treatment systems, laydown storage area, staff trailers and parking, storm water collection ponds, contact water holding ponds, and haul roads.

For site preparation, clearing and grubbing would be required across the entire Site D area with approximately 160 acres requiring tree removal.

It is assumed that most of the excavated soil and rock material would be used for grading, as needed, and for waste cover during landfill operations. The surplus excavated soil and rock material would be hauled (as it is excavated), dumped, and pushed into the X-611B Sludge Lagoon, which is located approximately 0.75 miles south of Site D.

8.3.2.1.4 Waste acceptance criteria

The WAC is comprised of the following seven components: (1) prohibitions resulting from ARARs or DOE operational needs, (2) activity criteria and chemical concentration criteria, (3) waste evaluation and characterization standards, (4) waste physical characteristics standards, (5) waste packaging standards, (6) waste safe handling standards, and (7) waste transportation standards. A waste stream must meet each component before being allowed to be disposed in a potential OSDC.

The first WAC component is ARAR and operational-based waste placement prohibitions that result from two mechanisms: (1) ARARs and (2) operational needs. All waste streams that are not allowed to be disposed in a potential OSDC as a result of one of these prohibitions are removed from further consideration.

Then each waste stream is evaluated against the activity and chemical concentration criteria and those that do not meet the criteria are not allowed to be disposed in a potential OSDC unless further treatment pursuant to defined requirements is performed. Groundwater fate and transport modeling along with an evaluation of potential contaminant concentrations likely to be present in D&D waste (RC-1) and other waste (RC-2, RC-3, and RC-4) streams show that there is a five order of magnitude safety factor between resultant protective numerical levels and the concentrations in the waste streams. This conclusion is primarily due to the favorable geologic conditions found at the proposed location of a potential OSDC along with the design elements of the cells.

However, any waste stream considered a hazardous waste must meet the regulatory treatment standards identified as ARARs. DOE is anticipating pursuing a CAMU designation for CAMU-eligible wastes via the forthcoming future Ohio Consent Decree document(s). The CAMU designation offers the opportunity to pursue adjusted treatment levels for principal hazardous constituents subject to Ohio EPA Director's approval based on the long-term protection offered by the engineering design of the potential OSDC. If the CAMU designation is approved, the treatment standards would be adjusted accordingly.

The other components of the WAC would be developed in detail as further design and operations plans are developed. Two design and operations documents would be developed and, upon Ohio EPA review and approval and/or concurrence, would become an enforceable part of the ROD should an on-Site alternative be selected. These documents would detail out the remaining WAC components defined in the DFF&O.

8.3.2.1.5 Potential OSDC operations

It is estimated that a 1.47 million-cy in-place volume of D&D waste/materials (RC-1), including 53,000 cy of residual soil (RC-1, EC-1), are expected to be generated under the DFF&O. Approximately 1.08 million cy of the D&D waste requiring fill (RC-1, EC-2) and all of the 53,000 cy of residual soil (RC-1, EC-1) are assumed to be disposed in a potential OSDC. Another 2.1 million cy of fill will be required. That fill volume rises to 2.2 million cy if a source of fill is the landfills (RC-3) which also contain some waste requiring fill (RC-3, EC-2). These volumes are in situ volumes, not transported or disposed volumes.

Waste destined for a potential OSDC would be adequately characterized, processed, inspected, and certified as meeting the potential OSDC WAC. In general, the operations phase would consist of bulk waste pickup at the generating areas by using open bed, off-road, articulating dump trucks, or by truck using large containers such as intermodals or discrete packaging such as B-25 boxes, drums, and bags. The trucks would transport the waste to the potential OSDC along a dedicated temporary haul road. Trucks carrying waste would enter the facility and proceed to the waste off-loading area within the potential OSDC. The transportation documentation (bill of lading, manifest) would be verified and waste packages would be inspected. The trucks would then proceed into the working face. Waste would be unloaded at the working face, pushed into the working face, spread, and compacted in accordance with waste placement requirements. Additionally, large items and containers would be transported to the potential OSDC via flatbed trailer and offloaded using heavy duty off-road fork trucks or a mobile crane, as appropriate. Waste would be loaded directly into the working face. A grid system within the disposal cells would be used for waste placement and tracking purposes. Placement information would be recorded daily upon receipt of waste in the disposal cell, as required by ARARs. This would facilitate waste reporting and mapping, as well as efficient use of disposal cell volume.

An IMTA, meeting ARARs, would provide storage capacity to accommodate higher than anticipated waste generation that exceeds the capacity for receipt or to accept waste deliveries during inclement weather when waste placement operations are curtailed. An IMTA could also be used to stockpile waste requiring fill (EC-2) to allow for the most effective co-placement of the waste forms with soil (EC-1). Waste placed in an IMTA would be reloaded into dump trucks or onto flatbed trailers and transported to the workface as described above.

Shear attachments or cutting equipment could be provided at the potential OSDC to assist in size reducing waste to reach the disposal requirements. Depending on the need, a centralized decontamination operation may occur at the potential OSDC or at another location also. Although not costed in the alternative, physical and chemical processes represent a variety of decontamination process options that may be used to remove contamination from waste to be disposed at a potential OSDC or to remove contamination from recyclable and/or reusable material.

To ensure waste received at the disposal facility could be properly handled, the physical form of the waste would be restricted. Bulk waste containers would be sized in accordance with the physical WAC so they could be handled and compacted in the disposal cell with standard earthmoving equipment. Large waste items, containers, and solidified items meeting the single-waste-item physical WAC could be accepted if special handling arrangements were made. Limitations on large waste/equipment would be developed to minimize void spaces in the disposal cell and prevent damage to the liner system. Generally, waste generators would use size reduction equipment at the D&D location to meet this requirement; however, a centralized size reduction operation to meet physical WAC requirements may occur at the potential OSDC under this alternative.

Bulk waste would be placed in nominal 1-ft lifts and be compacted using dozers and/or wheeled landfill compactors. Waste and containers would be placed to minimize possible damage to the geotextile layer and minimize void spaces after backfilling. Void spaces in the disposed waste would be filled with waste soil, clean soil, or flowable fill in order to reduce voids, achieve required compaction of the waste mass, and provide a stable base for waste transport vehicles dumping waste at the waste face. An EC-1/EC-2 ratio of 2:1 is assumed for normal operations. It is assumed that several waste faces would be active, and other areas of the cell would have temporary covers to provide containment and shielding and reduce water infiltration. If more accurate waste generation data indicate that exposures would not result in unacceptable risk, additional faces could be opened during periods of high disposal rates or when segregation of incoming waste streams is appropriate. Stationary and/or mobile water sprinkling units would be installed to control dust and minimize contaminant releases within the facility during operations. Dust control may also be achieved by using dust suppressant sprays as the waste is emptied from transport vehicles into the facility. The dust suppressant could be sprayed on finished surfaces of the cell floor and walls, stockpiles, and other areas (as needed). Additional measures would be implemented, as needed, such as water trucks to minimize dust generated from gravel roadways and interim cover material, including application of water and limitations on vehicle speed.

A series of temporary soil berms would be placed to separate the working face from clean soil surface areas of the disposal cell and those areas of the cells that had yet to receive waste. These berms would segregate collected precipitation that has not contacted disposed waste from collected precipitation that is potentially contaminated because of contact with waste. Precipitation accumulating in the working cells would infiltrate into the leachate collection system.

Operations other than waste handling would include providing heavy equipment maintenance and support facility maintenance such as roads and buildings. Appropriate personnel and equipment would be available to perform these operations.

The disposal facility would use a combination of telephone and radio communications, computers, and alarm systems to provide normal operations communication, traffic instructions, and immediate emergency instruction to operations and transport personnel. Normal construction emergency and fire suppression equipment would be available, and operations personnel would be trained in the use of this equipment. The potential OSDC operations would rely on the PORTS Fire Department and other on-PORTS first responders to control major fires or other emergencies.

All operations would be conducted in accordance with DOE Order 440.1, *Worker Protection Management for DOE Federal and Contractor Employees*, and 10 *CFR* 835 radiological requirements. Operations workers would wear proper PPE, including coveralls, gloves, sturdy shoes, and respiratory devices (as required). Transport vehicle operators would not leave their vehicles when in the exclusion area. Air quality would be monitored using continuous air monitors and grab samplers. The landfill operator would develop a training program compliant with applicable federal, state, and DOE training requirements. The training program and health and safety requirements would be designed to prepare employees to manage and maintain the disposal facility in a safe, effective, and environmentally sound manner. In addition, the landfill would develop a facility emergency plan that would describe hazards and the basic responses to upset and/or emergency conditions.

If there are extended periods when no waste would be disposed at a potential OSDC, a temporary cover would be placed over the waste to minimize dust and reduce water infiltration and leachate generation. When portions of the disposal cell had been filled to the final grade with waste, an interim cover would be installed.

In accordance with ARARs, groundwater monitoring would occur quarterly during waste disposal operations, utilizing the approved groundwater well network established. The list of monitoring constituents, sampling media, locations, frequency, and action levels would be defined in the Monitoring Plan as one of the design deliverables for a potential OSDC to be reviewed and approved by the Ohio EPA. Monitoring would include groundwater elevations and sufficient samples to represent the quality of groundwater beneath the cell, and allow for the detection of potential contamination should constituents migrate from the cell or support areas. Samples would be analyzed for both radiological and nonradiological constituents at an approved laboratory. An annual environmental monitoring report would be prepared to summarize sample collection and the analytical results.

8.3.2.1.6 Fill operations

Sufficient fill would be needed to meet the placement requirements for D&D waste requiring fill (RC-1, EC-2) as well as additional waste requiring fill (RC-3, EC-2) anticipated to be encountered during the generation of fill from contaminated borrow areas. It is assumed that two times as much fill as waste requiring fill would be used to meet requirements for long-term stability at a potential OSDC. Fill is used to minimize void spaces to lessen the potential for future waste subsidence. Waste subsidence could impact the long-term effectiveness of the final cap, so subsidence of the waste is to be avoided. Fill would be obtained from on-PORTS and/or off-PORTS sources. For the purposes of alternative evaluation, on-PORTS sources of contaminated fill are considered which potentially includes soil from deferred units (RC-2, EC-1).

Landfills (RC-3) and soil associated with contaminated groundwater areas (RC-2) are also potential fill sources that could produce large quantities of fill. While DOE does not expect to excavate Ohio Consent Decree plumes for groundwater remediation, those areas may be used to obtain additional fill. Should contaminated soil be used for fill at a potential OSDC, it should be noted that an estimated 223,000 cy of waste requiring fill (RC-3, EC-2) might be generated in the process of exhuming the landfills that overlie the contaminated soil. The presence of this waste (RC-3, EC-2) within these landfills would create the need for an estimated additional 446,000 cy of fill to support potential OSDC placement, of which all but 101,000 cy of fill (EC-1) is co-located in the landfills. In general, it is assumed that the clean cap/overburden would be excavated and set aside to support post-cleanup backfill requirements.

There is the potential that some of the contaminated fill or associated waste requiring fill (RC-2, RC-3) that is excavated cannot be disposed in a potential OSDC without treatment. Treatment and/or off-Site disposal of this material is included in this alternative, as appropriate. For the purposes of the alternative analysis, it is assumed that roughly 3,900 cy of waste is sent off Site for treatment (see Section 8.3.2.1.9) and/or disposal, and another 176,000 cy of soil (RC-2, RC-3, EC-1) is assumed to be treated. It is assumed for alternative evaluation that fill soil would contain TCE or other VOCs above treatment levels set under the CAMU regulation or would contain excess water. ARAR-compliant treatment technologies could be applied at the point of generation or at the potential OSDC and are likely to require only heavy equipment. However, once the treatment levels are set and the soil characteristics/volumes and schedule are developed during the design phase of the project, alternate technologies may be selected which might involve bringing treatment systems on Site. Some design treatability studies are likely to be required before an investment in purchasing or constructing larger treatment systems associated with treatment technologies such as low-temperature thermal desorption.

8.3.2.1.7 Potential OSDC capping and support facility dismantlement

It is assumed that final capping would occur shortly after disposal cells are filled to capacity. Other final activities would include installation of the permanent leachate treatment systems (including both the active system and passive system), removal of the interim leachate treatment system and other support facilities, and site restoration. Restoration could include removal of the sediment ponds, replacement of wetlands (if necessary), and grading and seeding of the disturbed areas outside the disposal cell to restore vegetation. Once the support facilities were removed and disposed in the last disposal cell, the facility would be capped with the permanent cover. The DFF&O requires submittal of a Draft Closure Plan, Completion of Remedial Action Report, and Closure Certification Report pursuant to the DFF&O subject to Ohio EPA review and concurrence and/or approval as applicable.

8.3.2.1.8 Post-operations surveillance and maintenance

During development of the support facilities, monitoring of the disposal facility and its environs would begin as soon as monitoring facilities were installed. Historic information and results from pre-operation monitoring would be used to develop a baseline for comparison with post-operation monitoring results. Surveillance, monitoring, and active maintenance would occur after the potential OSDC is capped. For cost-estimating purposes only, it is assumed these activities occur for a 30-year period. After that time, surveillance and monitoring continue but active maintenance ceases.

The post-operations activities and associated reporting requirements would be conducted in accordance with approved facility-specific S&M and monitoring plans. Activities would include the following:

- Surveillance: An integral part of post-operations care is surveillance and inspection. The potential OSDC would be inspected to verify adequate performance of the installed containment features and to alert DOE and regulatory agencies of any potential problems. The inspections would provide an early warning that specific elements may need more careful evaluation and monitoring.

  During the first year of operations, one or two inspections could be performed immediately after high-rainfall events to verify the effectiveness of water retention and transport systems and the accuracy of the performance predictions. Additional data should be collected after significant events (storm events of a 5-year intensity or greater). In the first 5 years after capping, inspections could be performed more frequently than in later years to evaluate seasonal effects on operation of the systems. Certain elements, such as disposal-cell stability, may require more frequent inspections. The timing of the inspections could be determined after evaluation of the first-year seasonal inspection results to provide the most useful information.

  After the fifth year of post-operations and upon completion of the first DFF&O 5-year review, inspection frequency could be adjusted as appropriate. Biennial or less frequent scheduled inspections may be acceptable for certain elements.

- Maintenance: Post-operations maintenance activities would include the clearing of uncontrolled plant growth from the disposal cell crest and side slopes; clearing, repair, and realignment of surface water transport structures; inspection and maintenance of the permanent leachate treatment system and passive leachate treatment system; replacement of signs; reestablishment of survey monuments; and collection of piezometer data. Undesired plant growth would be cleared annually, as needed. Ditch realignment, fence and sign repair, survey monument reestablishment, and other minor maintenance activities would be conducted on the basis of surveillance findings.

- Long-term Monitoring: Long-term media monitoring (groundwater, surface water, air, and biota) would be performed to detect potential releases from the disposal cell. Groundwater wells located upgradient and downgradient of the disposal cell would be sampled at least annually to monitor indicator radiological and nonradiological contaminant concentrations and determine whether there have been contaminant releases from the disposal cell. Continued monitoring would support 5-year reviews under the DFF&O (40 *CFR* 300.430 [f][4][V]). The surface water downstream from the disposal cell would be monitored to determine whether contaminant levels have changed over time. Surface water monitoring would be conducted during operation of the facility and through post-operations care in support of 5-year DFF&O reviews. A detailed monitoring plan would be developed during the potential OSDC design process, with Ohio EPA's input and approval.

- <u>Deed Restrictions and Environmental Covenant</u>: In accordance with ARARs and following the DFF&O, deed restrictions and an Environmental Covenant would be put into place to prohibit residential and industrial use of the property, construction of any facility that could damage the cover, or installation of groundwater extraction wells (for purposes other than monitoring). These deed restrictions and Environmental Covenant would also identify other administrative controls necessary to protect the public and the integrity of the disposal cell and would be referenced in a future deed, which would be filed with the appropriate local governmental authority.

8.3.2.1.9 Off-Site disposal

Alternative 2 includes off-Site disposal of some of the waste. All assumptions used to best represent an estimate for off-Site disposal cost and impacts are subject to change. Table 8.2 presented a summary of the various types and estimated volumes of waste that are currently assumed to be disposed off Site, either as a result of not meeting a potential OSDC's WAC, meeting an off-Site disposal Milestone, or as a result of being generated before a potential OSDC is approved in a ROD, available, or operational.

This section describes the common elements associated with off-Site disposal, whether in Alternative 2 or 3. DOE Manual 435.1-1, *Radioactive Waste Management*, establishes policies and minimum requirements by which DOE manages its radioactive waste, the radioactive components of MLLW, RCRA waste, and/or TSCA waste stemming from the cleanup and/or D&D of contaminated facilities (DOE 2001c). Chapter 1 of the manual specifically addresses the management of radioactive waste and states that LLW shall be disposed on the site of origin, if practical, or at another DOE facility if on-site disposal capacity is not available.

For PORTS actions that transfer wastes off Site, permits are required at the receiving facility. For the purposes of cost estimating and calculating transportation risk, the representative off-Site disposal locations used are NNSS, Energy*Solutions*, and Pike Sanitation Landfill. The MLLW disposal facilities at NNSS and Energy*Solutions* are permitted by Nevada and Utah, respectively. Also, all waste removed from PORTS must be disposed of, or treated at a disposal facility operating in compliance with the procedures for planning and implementing off-site response actions, as outlined in 40 *CFR* 300.440 (EPA's "off-site" policy). The purpose of this policy is to direct CERCLA wastes to disposal facilities determined to be environmentally sound and to avoid contributing to present and future environmental problems. In general, the following conditions must be met and verified by EPA to use an off-site receiving facility:

- The proposed receiving facility must be operated in compliance with all applicable federal, state, and local regulations; there must be no relevant violations at or affecting the receiving facility.

- There must be no releases from the receiving unit, and contamination from prior releases at the receiving facility must be addressed (as appropriate).

These bulleted conditions require a confirmation by the EPA regional office with jurisdiction over the chosen disposal facility. Specifically, this EPA office must confirm that the facility is acceptable for the receipt of PORTS waste covered by the DFF&O.

The DOE Consolidated Audit Program (DOECAP) is responsible for performing audits and assessments of all commercial and DOE treatment, storage, and disposal facilities that receive DOE waste. The DOECAP implements annual performance qualification audits of environmental analytical laboratories and commercial waste treatment, storage, and disposal facilities to support complex-wide DOE mission activities. First formulated in 2002, the intent of this corporate departmental program is to eliminate redundant audits by DOE field sites, achieve standardization, minimize DOE liabilities and risks, and reduce costs.

Characterization and Treatment

The waste generator would evaluate any process knowledge and review all existing waste characterization information to determine compliance with the characterization requirements and the WAC of the designated disposal facility. Wastes with inadequate characterization data would be sampled and analyzed as necessary. For wastes not meeting the designated facility's WAC or regulatory requirements regarding transportation or land disposal, the generator would be responsible for appropriate treatment and/or processing of the waste as described in the generating decision document. However, a centralized facility to meet transportation and disposal requirements, defined as one used by multiple projects, could be part of this alternative. Such a facility could include size reduction and/or decontamination process options to support off-Site disposal.

Packaging

Packaging requirements for wastes would be determined on the basis of waste form (other building waste, asbestos, concrete, soil, or PGE); waste type (LLW, mixed hazardous, RCRA/TSCA waste, construction and demolition debris, or solid waste); transportation mode; destination; economics; and other considerations.

For the purposes of this FS, purchasing waste packaging is included in this FS estimate, as are the rental costs of the transportation vehicles. To simplify the analysis, this FS assumes that most of the waste going to a commercial facility would be placed into 101-cy gondolas and filled with an average volume of 71 cy. Gondolas are easy to load and meet the containment requirements for most of the projected waste streams. The gondolas would be reused. Hazardous waste destined for a commercial facility would be packaged in 55-gal drums, B-25 boxes, or other small containers. These small containers would be disposed with the waste.

Most shipments to an industrial landfill would be bulk packaged in a triaxle dump truck or roll-off box and sent to the landfill.

For shipments to NNSS, several different disposal packages are required. The package used for PGE is driven by size of the components and the need to meet DOT requirements. The general package types required for Alternative 2 include the following:

- B-25 fissile boxes
- 25-cy Type A Intermodals
- 37-cy Type A Intermodals.

For estimating purposes, it is assumed that two packages can be loaded onto a truck, except for the 25-cy containers for which only one package is assumed loaded on a truck.

Local Transportation

In order to support rail shipments to a commercial facility, waste would need to be conveyed from the generator location to a rail siding. It is assumed that all intrasite shipments from the generator to a rail siding would use a dump truck or, in certain instances, a flatbed truck.

Off-PORTS Transportation

The following assumptions were used in this FS. Most of the LLW and mixed waste in Alternative 2 is assumed to travel by rail to a commercial facility for disposal. Shipments to the representative DOE facility, NNSS, would be via trucks. The assumed rail route to the representative off-Site commercial disposal facility, Energy*Solutions*, involves two major railroads (Norfolk Southern Railroad and Union Pacific Railroad) and is about 1,820 miles long. Rail shipments are typically manifested from destination to destination, and railroad companies may choose to make detours to pick up or deliver other railcars attached to the same train before delivering the waste to its destination. Actual waste transport miles traveled may be greater than the direct route mileage estimated. This would not affect transportation costs, but could affect transportation risk.

Disposal

Energy*Solutions* would unload the gondolas and intermodals. The waste would be transferred to Energy*Solutions* dedicated trucks, taken into the disposal cell, and emptied per approved procedures. The waste would be placed in the facility according to approved procedures similar to those described for a potential OSDC. Energy*Solutions* is required to perform external health physics surveys of the railcars and containers before shipment back to PORTS. Energy*Solutions* uses DOT limits for unrestricted (unlimited) release and for restricted (limited) release.

Disposal fees at Energy*Solutions* depend on: (1) the classification of the waste (LLW disposal fees are much less than mixed waste fees), (2) the form of the waste (soil [EC-1] disposal fees are less than non-soil [EC-2] fees), (3) the packaging, and (4) the mode of transportation (disposal fees for bulk shipments by truck are less than those for bulk rail shipments). All DOE waste shipped to Energy*Solutions* for disposal would follow the rate schedule established by contract through the DOE Office of Environmental Management (EM), Cincinnati Business Center. All MLLW treated to meet LDRs would be disposed in the Energy*Solutions* MLLW cell. The mixed waste disposal fees at Energy*Solutions*, used in the cost analysis for this alternative, are based on the tiered fee structure in an existing mixed waste disposal contract between DOE and Energy*Solutions*. The appropriate current contract pricing category was used.

The NNSS disposal facility is directly funded by DOE/National Nuclear Security Administration (NNSA). Therefore, no chargeback or fee to a project is applicable. However, to legitimately compare disposal alternatives, NNSS does have a value for their disposal capacity, and it is updated annually.

Pike Sanitation Landfill would receive construction and demolition debris or solid waste for disposal. This facility charges a flat rate for disposal by the truckload.

8.3.2.1.10 Recycling and/or reuse

DOE is committed to the recycling and/or reuse of materials generated through the D&D of the GDP facilities, in compliance with ARARs, irrespective of which remedial action alternative is selected. A commitment to recycling and/or reuse is therefore a component of the description of each of the remedial action alternatives. Prior to implementing recycling, DOE would evaluate and document the benefits (including disposal volume savings) against the additional costs of completing the action, implementing issues, and efforts with implementing associated policy issues. There can be costs associated with segregating and handling material, demonstrating the potentially recycled material is uncontaminated, or in decontaminating the material. DOE would evaluate the individual material and regulatory waste types throughout the implementation of the D&D, and recycle and/or reuse materials as appropriate.

DOE has preliminarily identified up to 110,000 cy of materials for which it may pursue recycling and/or reuse, including some amount of copper, nickel, stainless steel, concrete, and aluminum. For purposes of the development, evaluation, and comparison of alternatives in this RI/FS, the amount of recycling and/or reuse is assumed to be the same across the various action-based alternatives and is therefore not a discriminator in the comparison of the alternatives.

To prepare candidate materials for recycle and/or reuse, a number of commonly applied techniques have been identified in the process building RI/FS, including, but not limited to, crushing, size reduction, segmentation, segregation, storage, decontamination, characterization, and construction and operation of facilities to conduct and/or support such activities. Those discrete, limited activities conducted to prepare the material for recycling and/or reuse are generally part of the Process Buildings and Complex Facilities D&D Evaluation Project. However, recycling or reuse of materials at PORTS also could require the use of storage and/or a large-scale centralized chemical and/or thermal treatment process (e.g., nickel decontamination and metal melting). In parallel with the RI/FS and follow-on remedial design and implementation, DOE would potentially conduct treatability or pre-design studies to support the technical and economic evaluations of the merits of applying such a large-scale centralized treatment facility. Because this RI/FS discusses potential technologies, and because any selected recycling treatment option would be applicable to both alternatives and therefore impact neutral to the remedy selection process, it is envisioned that a later decision by DOE to implement a large-scale centralized facility would not constitute a significant alteration to the selected waste disposition remedy from a cost, scope, or schedule perspective.

If a centralized treatment facility is deemed appropriate to support a Site-wide treatment or recycle and/or reuse initiative, such a facility would be a component of Alternative 2 of the Site-wide Waste Disposition Evaluation Project. Considered for use in such a facility may be a number of decontamination techniques such as manual cleaning, pressure washing, chemical rinsing, grit or CO_2 blasting, laser etching, size reduction, storage, or any other activities as necessary to achieve required release standards. Such recycling and/or treatment must meet the definition of D&D as provided by the DFF&O. If recycling and/or treatment efforts do not meet the definition of D&D, DOE will need to seek applicable permits and authorizations.

8.3.2.2 Possibility of co-disposal of non-D&D waste (RC-2)

The DFF&O RI/FS SOW allows consideration of “Potential waste streams associated with environmental media cleanup activities to be conducted under the Ohio Consent Decree and for which DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste streams in any potential OSDC that might be constructed as a result of the Site-Wide Waste Disposition Evaluation project.” Under the Ohio Consent Decree, significant volumes of contaminated soil and associated groundwater still require a remediation decision. Excavation may be a major component of the remediation decision pursuant to the Ohio Consent Decree. The impacts and implications of up to an estimated 710,000 cy of non-D&D waste (RC-2) from the remaining environmental cleanup activities are considered.
The 710,000 cy is an estimate established for the purposes of conducting a complete and thorough evaluation of the alternatives. The actual volume of any non-D&D waste (RC-2) would be determined based on several factors, including the fact that the remediation decision may not be excavation.
The decision to excavate or dispose of the non-D&D waste (RC-2) is not being made under this project.

8.3.3 Description of Alternative 3

The following GRAs and process options that were identified as representative process options in Section 7 have been used to describe Alternative 3:

- Centralized Treatment
    - Size and void reduction
    - Decontamination.

- Off-Site Disposal
    - DOE off-Site facility
    - Permitted commercial facilities.

- Recycle and/or Reuse

- Waste Transportation
    - Truck
    - Train.

Alternative 3 would provide for the transportation of D&D waste (RC-1) streams off Site to one or more approved disposal facilities and placement of the wastes in those facilities. The alternative must comply with only applicable requirements. Wastes requiring disposal may be construction and demolition debris, solid waste, or it may contain radionuclides, RCRA-hazardous components, and TSCA-defined components either singularly or in combination. Although some level of waste characterization and classification has been conducted for a portion of the expected wastes, additional waste-stream-specific characterization would be required to determine compliance with off-Site disposal facilities' WAC (as well as for any on-Site disposal facility WAC). Characterization of future D&D (RC-1) waste and/or RC-4 waste may result in different volumes or waste classifications than those forecasted for use in this FS.

As described in Section 4.1, candidate PORTS waste streams are classified as follows:

- LLW
- Hazardous waste
- TCSA chemical waste
- Construction and demolition debris
- Solid waste
- Mixed waste with combinations of LLW, RCRA waste, and/or TSCA waste.

The anticipated waste forms include the following:

- Soils
- Concrete
- Asbestos
- PGE (e.g., converters, compressors, and coolers)
- Other building waste.

There are also materials with high potential for recycling and/or reuse. The volumes for the various waste forms disposed off Site in Alternative 3 are presented in Table 8.3.

Table 8.3. D&D Waste (RC-1) Disposition Volumes

D&D Waste (RC-1) Form Description	In Situ volume (cy)	Disposed Off Site in Alternative 3 (cy)
Residual Soil (EC-1)	53,000	53,000
Concrete, asbestos, other building waste (EC-2)	1,032,000	1,032,000
PGE (EC-2)	272,000	99,000[a]
Targeted Recyclable Material	110,000	110,000
Total DFF&O Waste (RC-1) and Recyclables	**1,467,000**	**1,294,000**

Note:
[a] Much of the PGE is segmented, resulting in a volume reduction for disposal. A greater volume reduction effort is assumed for off-Site disposal than on-Site disposal.

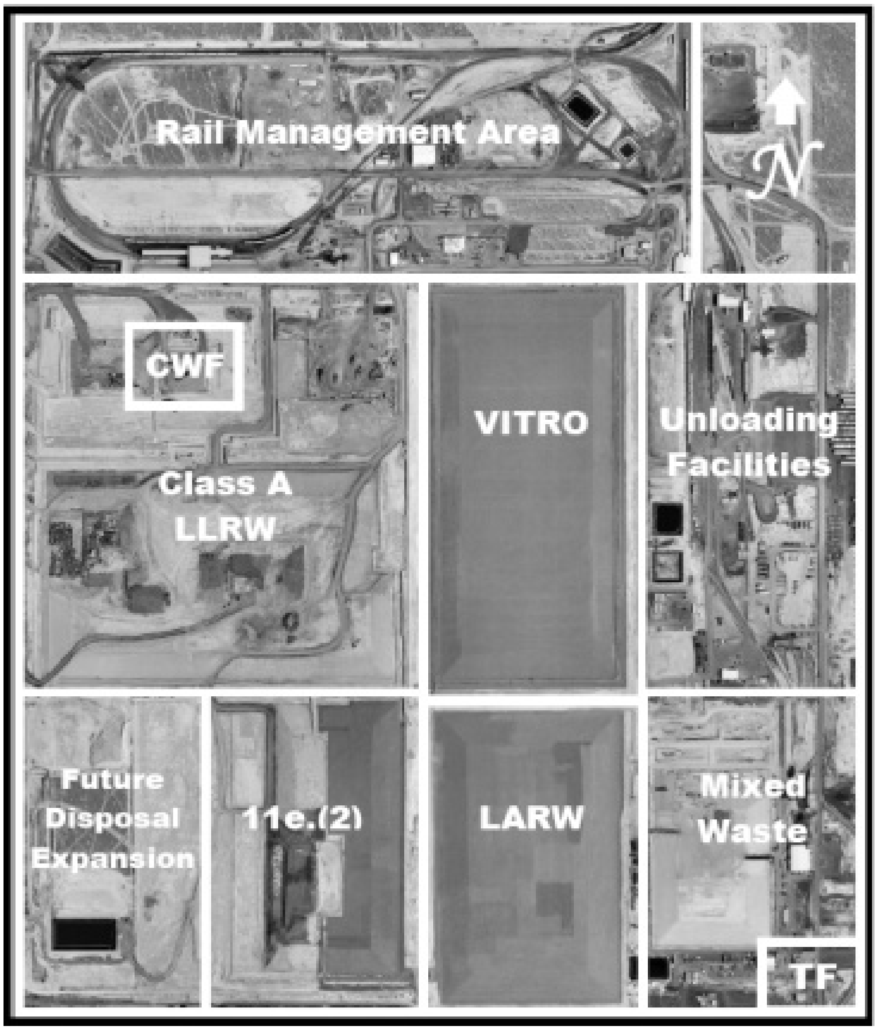
D&D = decontamination and decommissioning
DFF&O = *The April 13, 2010 Director's Final Findings and Orders for Removal Action and Remedial Investigation and Feasibility Study and Remedial Design and Remedial Action, including the July 16, 2012 Modification thereto*
EC = engineering category
PGE = process gas equipment
RC = regulatory category

As in the case of the on-Site disposal alternative, the projects generating the waste would be responsible for making decisions on any treatment required to meet WAC, loading/packaging of the waste at the point of origin, and characterizing and profiling the waste (as required) to demonstrate that potential waste streams would meet the receiving facility WAC. The Site-wide Waste Disposition Evaluation Project decision is responsible for planning and costing local transportation, all conveyances (trucks and railcars), disposal fees, and any need for centralized treatment to support recycling and/or reuse. Packaging would be conducted in conformance with the DOE and DOT regulations for the chosen mode of transportation and would also comply with the designated disposal facility's WAC. The wastes would be transported off Site via rail or truck, depending on economics and the capabilities of the receiving facility.

Section 8.3.3.1 describes the disposal locations that were selected to represent off-Site disposal. These locations are only used in the evaluation of alternatives. The landfill conditions; WAC; and treatment, packaging, and transportation elements are all discussed. Then, Section 8.3.3.2 describes the waste volumes, numbers and types of packaging, and transportation miles that apply to Alternative 3.

8.3.3.1 Description of off-Site disposal facilities

Energy*Solutions* Waste Disposal Facility Description. The Energy*Solutions* waste disposal facility is located in Clive, Utah, approximately 75 miles west of Salt Lake City, Utah. It is licensed and permitted to receive for disposal naturally occurring radioactive material (NORM), LLW, uranium/thorium mill tailings, RCRA hazardous waste, and mixed waste. The facility is located in a remote desert with low annual precipitation (9.6 in.); over stagnant, nonpotable groundwater; and within a 100-mile hazardous waste zone established by the State of Utah. The nearest population center is approximately 40 miles away. Energy*Solutions* offers a variety of mixed waste treatment processing options. Waste transportation to Energy*Solutions* can be either by highway or railway. Figure 8.5 is a plan view of the Energy*Solutions* facility in Clive.



CWF = Containerized Waste Facility
LARW = Low-Activity Radioactive Waste
LLRW = Class A Low-Level Radioactive Facility
TF = Treatment Facility

Figure 8.5. Plan View of the Energy*Solutions* Radioactive Disposal Facility

The VITRO cell in the center of the facility is a DOE-owned uranium mill tailings pile that generally established the location as a radioactive waste disposal complex. The balance of the facility is owned and operated by Energy*Solutions*.

The disposal facility is an above-grade, 1,000-year design with four lined disposal cells to segregate 11.e(2) waste (uranium and thorium mill tailings), radioactive waste, mixed waste, RCRA hazardous waste, NORM, and naturally accelerator-produced radioactive material. The liner of the facility contains a natural clay foundation and a clay layer with a leachate collection/detection system. The cap contains a 7-ft clay radon barrier, a rock filter zone, and a coarse rock erosion barrier. The waste is deposited in 12-in. layers and then compacted.

Waste Treatment. Energy*Solutions* offers a number of treatment options for mixed waste, including stabilization/solidification, oxidation/reduction, fixation, deactivation, neutralization, and micro/macroencapsulation. Size reduction and separation processes are available for soil, two-phase sludges, slags, and debris. These processes are applicable to most RCRA-characteristic and RCRA-listed waste streams. For an additional cost, waste can be shipped to the facility and treated there before disposal.

Waste Packaging. All waste packaging must meet DOT regulations. Packaging options acceptable at Energy*Solutions* include bags, boxes, drums, gondola railcars, dump trucks, Sea-Land containers, intermodal containers, and roll-off containers. Other containers are acceptable on a case-by-case basis. Bulk shipment of wastes is accepted in lined trucks or railcars that provide containment without additional packaging.

The waste packaging options are usually dictated by the mode of transportation selected, the characteristics of the wastes, and economic considerations. With a few exceptions, the packaging considerations for both rail and truck transportation are identical. B-25 boxes, intermodal containers, and drums are examples of waste packaging that is applicable to both truck and rail conveyance of waste. Bulk containers are single-use containers typically disposed with the waste. Each waste stream would be evaluated individually to determine the most effective packaging option.

Transportation. Energy*Solutions* is capable of receiving both truck and rail shipments, and there are no limitations on the number of trucks or railcars accepted each day. Railcars can be unloaded in bulk with a gondola unloading device. Truck transportation routes to Energy*Solutions* range from 1,897 to 1,993 miles from PORTS with travel durations of 38 to 41 hours. Rail transportation routes to Energy*Solutions* would vary depending on the rail company selected to ship the waste. An estimate of 1,820 miles from PORTS to Energy*Solutions* is used in this FS.

PORTS has excellent rail access, and several track configurations (switching capabilities) are possible. There are approximately 17 miles of track that lie within the boundaries of PORTS. However, only approximately one-third of the tracks are currently in service. The Norfolk Southern rail line is connected to the CSX main rail system via a rail spur entering the northern portion of the plant. Track in the vicinity of Piketon, Ohio, allows a maximum speed of 60 mph. The CSX system also provides access to other rail carriers.

Between 1999 and 2010, PORTS shipped and disposed approximately 52,000 cy of LLW soil and waste and approximately 6,700 cy of mixed waste at the Energy*Solutions* facility in Clive from environmental restoration and legacy waste management projects.

Documentation and Characterization Requirements. Based on applicable regulations, Energy*Solutions* imposes specific documentation and characterization requirements on waste shipments. Before accepting a waste shipment, Energy*Solutions* staff review documentation on the waste and evaluate representative samples. Waste acceptance is based on the following:

- The waste profile record that documents the physical, chemical, and radiological characteristics of the waste, and delineates waste properties relative to hazardous waste management regulations and prohibitions
- A certification of presence or absence of other types of hazardous and toxic substances such as pesticides, herbicides, and PCBs
- A statement defining whether the waste is subject to or in compliance with RCRA LDRs

- Representative samples of the waste

- Laboratory analytical results.

Table 8.4 shows the analytical requirements imposed by Energy*Solutions*.

Table 8.4. Analytical Requirements for the Energy*Solutions* Disposal Facility

Gamma spectroscopy
Uranium/thorium isotopic
TCLP
Total organic halides
Hydrogen sulfide/cyanide
Soil pH
Paint filter test
Standard proctor

TCLP = Toxicity Characteristic Leaching Procedure

Before receiving shipments, Energy*Solutions* performs the analyses shown in Table 8.4 and others, as required, to ensure that waste meets incoming acceptance parameters and to establish incoming shipment tolerances. Energy*Solutions* or an independent third party may conduct chemical screening analyses, but the radiological analyses must be conducted by a third party. Additional required documentation includes the following:

- Radiological evaluation form
- Physical properties evaluation form
- Radioactive waste shipment and disposal form
- Uniform hazardous waste manifest form
- Waste certification form
- DOE/NRC Form 741 (radiological equivalent of the hazardous waste manifest).

Nevada National Security Site Description. The NNSS (formerly the Nevada Test Site) is a DOE reservation located approximately 65 miles northwest of Las Vegas, Nevada. It served as the nation’s primary location for the development and testing of nuclear weapons and related experiments from 1951 to 1992. Existing facilities and infrastructure enable the execution of operations and experiments in support of the nation’s Stockpile Stewardship Program and the new National Center for Nuclear Security.

There is also an ongoing EM mission at the NNSS that includes the Area 5 Radioactive Waste Management Complex (RWMC), a radioactive waste management and disposal facility where LLW and MLLW are safely and permanently disposed. The Area 5 RWMC is located in one of the most arid and least populated regions of the United States, which provides an ideal area for near-surface disposal of LLW and MLLW. Annual potential evapotranspiration is approximately 15 times annual precipitation. Approximate annual precipitation is 5 in. Accumulation of chloride in the vadose zone indicates that percolation of rainwater below the root zone ceased at least 10,000 to 15,000 years ago. The saturated zone occurs more than 790 ft below the surface. The median travel time through the thick, dry vadose zone is estimated to be greater than 50,000 years (NNSS 2011). Transport of contaminants to the uppermost aquifer is extremely unlikely under current climatic conditions.

Figure 8.6 is a plan view of the NNSS Area 5 RWMC. Area 5 accepts LLW and MLLW for disposal. Both LLW and MLLW can be classified waste. NNSS has another LLW disposal facility in Area 3; however, it is on standby until additional volume and/or surge capacity is required.

Figure 8.6. Plan View of the NNSS RWMC Area 5 Disposal Facility

The NNSS is authorized to receive DOE-generated LLW under its AEA authority as implemented by DOE Manual 435.1-1 requirements, as well as DOE-generated RCRA hazardous waste and mixed waste. The hazardous and mixed wastes are disposed in a separate lined disposal facility co-regulated by DOE and the State of Nevada.

Waste Treatment. NNSS cannot accept off-site hazardous waste for chemical treatment. All waste must be LDR compliant before shipping to, and acceptance by, NNSS. Further, NNSS cannot accept off-site waste requiring additional physical treatment (such as shearing or cutting).

Waste Packaging. All waste packaging must meet DOT regulations. Packaging options acceptable at NNSS include bags, boxes, drums, and dump trucks, Sea-Land containers, intermodal containers, and roll-off containers. Other containers are acceptable on a case-by-case basis. Bulk shipment of wastes is accepted in lined trucks that provide containment without additional packaging. The waste packaging options are dictated by the mode of transportation selected, the characteristics of the wastes, and economic considerations. Containers are typically disposed after receiving at NNSS. These containers include B-25 boxes, intermodal containers, and drums. Each waste stream must be evaluated individually to determine the most effective packaging option.

Transportation. NNSS is capable of receiving only truck shipments at Area 5. Generators may ship by rail to a transload facility relatively close to the NNSS. The railcars are unloaded, and the waste is subsequently delivered by truck to the NNSS Area 5 disposal area. This FS assumes only truck shipments to NNSS due to evaluations of costs and schedule in past projects. The facility can receive trucks daily except for Friday through Sunday, unless they are received under unique circumstances. Truck transportation routes to NNSS are approximately 2,200 miles from PORTS with travel durations of 30 to 50 hours, most often depending on whether the transported waste is classified waste or not.

One federal highway (U.S. 23) and one state highway (State Highway 32) serve the PORTS area. Both highways are located within 1 mile of PORTS. Both routes are four-lane highways with U.S. 23 traversing north-south and State 32 traversing east-west. PORTS is located approximately 3.5 miles southeast of the interchange between U.S. 23 and State 32. From 2007 data (Ohio Department of Transportation 2011), U.S. 23 has an average daily traffic volume of 14,490 vehicles, and State 32 has an average daily traffic volume of 7,700 vehicles. Traffic in both directions is included in these values.

The PORTS road system is in generally good condition; however, the roads require frequent maintenance and repaving. Except during shift changes, traffic volumes on the plant access roads and Perimeter Road are low. Peak traffic volume occurs during shift changes, and the principal traffic problem areas during peak morning/afternoon traffic occur at locations where parking lot access roads meet Perimeter Road.

Between FY 2000 and 2009, PORTS shipped approximately 51,000 cy of waste to NNSS for disposal, including approximately 34,000 cy of classified waste.

Waste leaving PORTS and destined for the NNSS would travel west, eventually merging into Interstate-40 and entering Nevada south of Las Vegas, Nevada. Under no circumstances are waste transports allowed to traverse downtown Las Vegas roadways.

Documentation and Characterization Requirements. NNSS has disposal capacity for mixed waste as well as for LLW. Since 2005, NNSS has accepted DOE mixed waste for disposal. A new mixed waste disposal facility went on-line in 2011 with 30,000 cy of disposal capacity. The current permit for MLLW disposal ends in 2015, but it could be extended if capacity is not fully used (National Security Technologies 2011). All RCRA mixed hazardous waste must meet LDRs prior to acceptance for disposal at NNSS (NNSS 2011).

Based on DOE Order 435.1, the NNSS WAC, and applicable regulations, NNSS imposes specific documentation and characterization requirements on waste shipments. Waste is first characterized in accordance with SW-846 and the NNSS WAC. A waste profile is developed and submitted to the Waste Acceptance Review Panel, an integrated team of DOE, contractor, and regulator subject matter experts who review and comment on draft profiles. After profile acceptance, waste is packaged in accordance with procedures and witnessed by the NNSS Waste Certification Officer.

Waste acceptance is based on the following:

- The waste profile record that documents the physical, chemical, and radiological characteristics of the waste, and specific to hazardous or mixed waste, the profile that delineates waste properties relative to hazardous waste management regulations and prohibitions

- A statement defining whether the waste is subject to or in compliance with RCRA LDRs

- Split samples that may be required or requested, depending on the complexity or uncertainty of specific waste streams (Radioactive Waste Acceptance Program may provide oversight of the split sampling event)

- Once the container or conveyance is closed, no additional samples are usually taken at either the generator location or at NNSS.

Only generators with an approved NNSS Waste Certification Program may ship to NNSS. PORTS is currently an approved generator. Additional required program and/or waste stream-specific profile documentation includes the following:

- QA Program Plan and procedures
- NNSS WAC Implementation Crosswalk
- Waste certification personnel list
- Uniform hazardous waste manifest form
- Waste certification form.

Pike Sanitation Landfill Description. Pike Sanitation Landfill is a private and commercial landfill located in Piketon, Ohio. This facility is located about 5 miles due north of PORTS along State Route 220. The facility is regulated by Ohio EPA.

This disposal facility is a RCRA Subtitle D design, and it is only permitted to accept solid/sanitary waste. The facility cannot accept radioactive waste, RCRA-regulated hazardous waste, or TSCA-regulated waste (such as PCBs or asbestos) for disposal.

Waste Treatment. The generator may not ship treated RCRA characteristic waste to Pike Sanitation Landfill. No treatment capability exists at the landfill.

Packaging. All waste packaging must meet DOT regulations. Container types acceptable at the Pike Sanitation Landfill facility include drums, roll-off boxes, roll-off and dump trailers, box trailers, bulk tank trailers, and flatbed or lowboy trailers. Other container types are accepted on a case-by-case basis. Typically, waste is shipped to the landfill in 20-cy triaxle dump trucks.

Transportation. Pike Sanitation Landfill is capable of receiving truck shipments only. PORTS contractors have shipped solid or construction and demolition debris waste to the Pike Sanitation Landfill facility in the past, so the waste acceptance process and shipping logistics are well understood. Historical waste shipped to the Pike County Landfill originated from D&D of administration buildings at PORTS. This waste was known to be “clean” and had no regulated concentrations of hazardous or radioactive constituents.

Documentation and Characterization Requirements. Pike Sanitation Landfill will enter into disposal agreements with waste generators only when their wastes are considered to be acceptable for management. As required, prequalification waste analysis is used to determine whether the waste is acceptable for disposal or must be shipped to an alternative facility. It is also used to determine proper material handling requirements. All received wastes are compared with the prequalification analysis to determine whether they are consistent with the initial analysis. The prequalification analysis can be performed at the landfill or at an off-site facility. This mandatory analysis, performed on all pre-acceptance and incoming waste samples, includes a physical description, pH screening, water mix screening, flammability potential screening, cyanide and sulfide screening, radioactive screening, and PCB screening for oil-bearing wastes.

8.3.3.2 Detailed description of off-Site alternative

The off-Site disposal alternative consists of disposing four major components defined by the expected PORTS D&D waste (RC-1) forms illustrated in Section 4.1. These components are as follows:

- PGE (converters, compressors, coolers, some piping, valves, surge drums), assumed to be nearly all LLW, would be primarily shipped to NNSS.
- Metal or other material with a high probability for recycle and/or reuse would be stored on Site pending processing by a recycle and/or reuse vendor.
- Nonradiologically-contaminated and nonhazardous waste would be shipped to Pike Sanitation Landfill.
- The balance of LLW and/or MLLW generated by D&D would be shipped to a commercial facility (assumed to be the Energy*Solutions* disposal facility in Clive, Utah).

Disposal Location. Whole converters and compressors are expected to be classified waste. Because classified waste must be maintained under DOE controls, only NNSS is considered for PGE disposal. The specific in situ volume of waste proposed to be shipped to NNSS is 272,000 cy.

Most non-PGE waste, by volume, would be shipped in bulk by rail to a commercial facility. An evaluation of transportation by truck was performed to compare against rail transportation. Rail transportation is much less expensive and more efficient for transport and is therefore used in this FS.

All of the named "representative" waste disposal facilities have sufficient disposal capacity to receive the projected waste volumes. Table 8.5 provides the estimated volumes that would be disposed at Energy*Solutions*, NNSS, and Pike Sanitation Landfill under Alternative 3 by regulatory waste type. The waste forms include asbestos, concrete, PGE, and other building waste and soils. All hazardous (RCRA), or mixed LLW/RCRA waste is assumed to meet LDRs prior to disposal. The volumes could change as a result of varying waste types and volumes than those originally planned, alternate disposal locations being selected during design, decontamination efforts being employed to allow more of the waste to go to a nearby disposal facility, or additional recycle and/or reuse efforts.

Table 8.5. Off-Site Alternative (Alternative 3) Disposition Plan

Disposal Location	D&D Waste (RC-1) Types and Form		In Situ Volumes (cy)
Recycled/Reused	Material only	--	110,000
Energy*Solutions*	LLW and/or MLLW	EC-1	53,000
		EC-2	794,000
NNSS	PGE LLW and/or MLLW	EC-1	0
		EC-2	272,000
Pike Sanitation Landfill	Construction and demolition debris/ solid waste	EC-1	0
		EC-2	240,000
		Total	**1,467,000**

EC = engineering category
LLW = low-level (radioactive) waste
MLLW = mixed low-level radioactive waste
NNSS = Nevada National Security Site
PGE = process gas equipment
RC = regulatory category

Characterization and Treatment. The waste generator would review all existing waste characterization information to determine compliance with the characterization requirements and WAC of the designated disposal facility. Wastes with inadequate characterization data would be sampled and analyzed as necessary. For wastes not meeting the designated facility's WAC or regulatory requirements regarding transportation or land disposal, the generator would be responsible for appropriate treatment and/or processing of the waste. Based on economic and other considerations, the generator, under a generating decision document, could choose to treat the waste at the generator area, a central facility at PORTS, a commercial facility, or the off-Site disposal facility. However, a centralized facility to meet transportation and disposal requirements, defined as one used by multiple projects, would be part of this alternative. Such a facility could include size reduction and/or decontamination process options to support off-Site disposal.

Packaging. Packaging requirements for wastes originating at each generator area would be determined based on waste form, PGE, other building waste, concrete, soil, or metal; waste type (LLW, mixed waste, RCRA/TSCA waste, construction and demolition debris, or solid waste); transportation mode; destination; economics; and other considerations.

Purchasing or renting packages or containers that are reused, such as intermodals and trucks, is included in this FS estimate. To simplify the cost analysis, this FS assumes that all LLW going to a commercial facility would be placed into 101-cy gondolas and filled with an average volume of 71 cy. Gondolas are easy to load and unload. Dump trucks would move the waste to a rail yard where the loading would occur. Hazardous waste destined for a commercial facility would be packaged in 55-gal drums, B-25 boxes, or other small containers. These small containers would be disposed with the waste.

For shipments to Pike Sanitation Landfill, all waste would be transported in dump trucks. A total of 15,600 truckloads would be required to dispose 240,000 cy (in-place volume) of assumed solid or construction and demolition debris waste under the off-Site alternative.

For shipments to NNSS, several different disposal packages are required. The package used for PGE is driven by size of the components and the need to meet DOT requirements. The general package types required for Alternative 3 include the following:

- B-25 fissile boxes
- 25-cy Type A Intermodals
- 37-cy Type A Intermodals.

For estimating purposes, it is assumed that two packages are loaded onto a truck, except for the 25-cy containers (one loaded per truck).

Although a wider variety of packages may be used at the generator area and be acceptable at the disposal facility, these packaging assumptions represent a best value for packaging and a moderate cost for receiving and unloading the packages at the disposal facility.

Local Transportation. In order to support rail shipments to Energy*Solutions*, waste would need to be conveyed from the generator location to a rail siding. It is assumed that all intrasite shipments from the D&D location to a rail siding would use a dump truck or, in certain instances, a flatbed truck.

Using an assumption of roughly 20 cy per truck, it is assumed that 80,400 local truck trips would be needed to support the rail shipments to Energy*Solutions*.

Off-Site Transportation. The following assumptions were used in this FS. When full (considering the weight capacities of the containers and the transport vehicles), each container would be placed onto a dump truck or flatbed trailer at the generator area. To identify the waste types and associated hazards, the waste containers would be manifested and placarded according to RCRA, DOT, and DOE requirements before placement on the trucks.

For Alternative 3, most (85 percent) of the LLW and mixed waste is assumed to travel by rail to a commercial facility for disposal. PGE would be shipped to NNSS by truck. The assumed rail route to Energy*Solutions* involves two major railroads (Norfolk Southern Railroad and Union Pacific Railroad) and is about 1,820 miles long. The shipment would start at PORTS with Norfolk Southern, which provides rail service to PORTS. Improvements to the PORTS rail yards would be needed to support the loading operation and are included in this alternative.

Rail shipments are typically manifested from destination to destination, and rail companies may choose to make detours to pick up or deliver other railcars attached to the same train before delivering the waste to its destination. Actual waste transport miles may be greater than the estimated direct route mileage. This would not affect transportation costs, but may affect transportation risk.

Table 8.6 summarizes waste shipments from PORTS to the western United States.

Table 8.6. Alternative 3, Total Miles and Trips to Energy*Solutions* and NNSS

Truck Miles to NNSS	Truck Trips to NNSS	Railcar Miles to ES	Railcar Shipments to ES
42,799,000	9,727	49,919,000	13,714

ES = Energy*Solutions*
NNSS = Nevada National Security Site

The total number of actual train loads would depend on the number of railcars per train. It is assumed that 55 railcars would make up one unit train to Energy*Solutions*. The number of required railcars would vary depending on the rate of waste delivery to the rail spur loading area. Because the lease fee would be paid monthly, the number of railcars rented by DOE would change as the rate of waste generation changes.

Disposal. Energy*Solutions* would unload the gondolas and intermodals, transferring the waste to Energy*Solutions*' dedicated trucks; take it into the disposal cell; and empty it per approved procedures. The waste would be placed in the facility according to approved procedures similar to those described for the potential OSDC. Energy*Solutions* is required to perform an external health physics survey of the railcars and containers before shipment back to PORTS. Energy*Solutions* uses DOT limits for unrestricted (unlimited) release and restricted (limited) release.

Disposal fees at Energy*Solutions* depend on: (1) the classification of the waste (LLW disposal fees are much less than mixed waste fees), (2) the form of the waste (soil [EC-1] disposal fees are less than non-soil waste [EC-2] fees), (3) the packaging, and (4) the mode of transportation (disposal fees for bulk shipments by truck are less than for bulk rail shipments). It is conservatively assumed that all mixed waste would remain classified as mixed waste even after treatment to meet LDRs. The mixed waste disposal fees at Energy*Solutions*, which are used in the cost analysis for this alternative, are based on the tiered fee structure in an existing mixed waste disposal contract between DOE and Energy*Solutions*.

The NNSS disposal facility is directly funded by DOE/NNSA. Therefore, no chargeback or fee is applicable. However, to legitimately compare disposal alternatives, NNSS does have a value for their disposal capacity, and it is updated annually.

Pike Sanitation Landfill would receive construction and demolition debris and solid waste for disposal. A flat rate for disposal by the truckload is charged at this facility.

Management of Waste Exceeding Off-Site Disposal WAC. All waste disposed under the off-Site alternative would be required to satisfy the appropriate facility WAC. Some waste streams may be decontaminated to meet the WAC. Decontamination could consist of physical processes such as scabbling or even chemical processes such as dissolution. Most of this decontamination would be part of the decision for generating the waste. However, decontamination to change large volumes of waste from LLW or hazardous waste to merely construction and demolition debris or solid waste regulated under the Ohio Solid Waste regulations could be implemented under this alternative. The decontamination would be employed to meet the WAC of a lower protection disposal facility if it proves advantageous to the project.

If an off-Site facility that can accept a certain waste stream (even after decontamination) is not identified, that waste stream would require interim storage until treatment or disposal capacity becomes available. Based on projected contaminant data (see Section 4.2) and the WAC for the representative off-Site disposal facilities, it is assumed that all waste streams would satisfy appropriate off-Site disposal facility WAC.

It is possible, however, that some of the mixed waste or LLW would not meet the Energy*Solutions* WAC for radionuclides. The volume of waste exceeding Energy*Solutions* WAC for radionuclides would likely be a very small percentage of the total volume of LLW and mixed waste. It is also possible that other LLW/MLLW disposal facilities could accept the higher activity waste if it did not contain or could be treated to eliminate any RCRA or TSCA hazardous components. Because the expected volumes of such waste streams are small and the resulting cost differential between disposal options is also small, management of waste exceeding WAC is not analyzed in detail in this FS.

Recycling and/or Reuse. The recycling and/or reuse component and opportunities of this alternative are the same as those discussed for Alternative 2. DOE is committed to the recycling and/or reuse of materials generated through the D&D of the GDP facilities, in compliance with ARARs, irrespective of which remedial action alternative is selected. A commitment to recycling and/or reuse is therefore a component of the description of each of the remedial action alternatives. Prior to implementing recycling, DOE would evaluate and document the benefits (including disposal volume savings) against the additional costs of completing the action, implementing issues, and efforts with implementing associated policy issues. There can be costs associated with segregating and handling material, demonstrating the potentially recycled material is uncontaminated, or in decontaminating the material. DOE would evaluate the individual material and waste types throughout the implementation of the D&D and recycle and/or reuse materials as appropriate.

DOE has preliminarily identified up to 110,000 cy of materials for which it may pursue recycling and/or reuse, including some amount of copper, nickel, stainless steel, concrete, and aluminum. For purposes of the development, evaluation, and comparison of alternatives in this RI/FS, the amount of recycling and/or reuse is assumed to be the same across the various action-based alternatives and is therefore not a discriminator in the comparison of the alternatives.

To prepare candidate materials for recycle and/or reuse, a number of commonly applied techniques have been identified in the process building RI/FS, including, but not limited to, crushing, size reduction, segmentation, segregation, storage, decontamination, characterization, and construction and operation of facilities to conduct and/or support such activities. Those discrete, limited activities conducted to prepare the material for recycling and/or reuse are generally part of the Process Buildings and Complex Facilities D&D Evaluation Project. However, recycling and/or reuse of materials at PORTS also could require the use of storage and/or a large-scale centralized chemical and/or thermal treatment process (e.g., nickel decontamination and metal melting). In parallel with the RI/FS and follow-on remedial design and implementation, DOE would potentially conduct treatability or pre-design studies to support the technical and economic evaluations of the merits of applying such a large-scale centralized treatment facility. Because this RI/FS discusses potential technologies and because any selected recycling treatment option would be applicable to both alternatives and therefore impact-neutral to the remedy selection process, it is envisioned that a later decision by DOE to implement a large-scale centralized facility would not constitute a significant alteration to the selected waste disposition remedy from a cost, scope, or schedule perspective.

If a centralized treatment facility is deemed appropriate to support a Site-wide treatment or recycle and/or reuse initiative, such a facility would be a component of Alternative 3 of the Site-wide Waste Disposition Evaluation Project. Considered for use in such a facility, technologies may use a number of decontamination techniques such as manual cleaning, pressure washing, chemical rinsing, grit or CO_2 blasting, laser etching, size reduction, storage, or any other activities as necessary to achieve required release standards. Such recycling and/or treatment must meet the definition of D&D as provided by the DFF&O. If recycling and/or treatment efforts do not meet the definition of D&D, DOE will need to seek applicable permits and authorizations.

HIGHLIGHTS OF SECTION 8

- Three alternatives are developed: no action, on-Site disposal, and off-Site disposal.
- Numerous assumptions were generated to support the evaluation of alternatives. They will be revisited in subsequent phases of the project.
- A potential OSDC at Site D can accept up to 5 million cy of waste and fill material (total capacity); the on-Site disposal alternative includes off-Site disposal of some waste streams.
- The draft modeled WAC are developed for the greatest volume assumption and for all potential waste streams.
- There is plentiful capacity at off-Site disposal locations for both volumes.
- Recycling and/or reuse is a key component of each alternative and is the same in both.

NEXT STEP: SECTION 9 COMPLETES THE FS PHASE OF THE PROJECT

BY EVALUATING THE ALTERNATIVES

9. DETAILED ANALYSIS OF ALTERNATIVES

This section presents the detailed analysis of the no-action and on- and off-Site disposal alternatives described in Section 8. The detailed analysis evaluates the advantages and disadvantages of the range of alternatives to provide the basis for identifying the preferred alternative in the Proposed Plan and the selected remedy in the ROD.

The detailed analysis consists of individual and comparative analyses. After the evaluation criteria are introduced in Section 9.1, Section 9.2 provides the individual analysis and Section 9.3 provides the comparative analysis. Building on the detailed alternative descriptions, the individual analysis provides an in-depth evaluation of each alternative against the threshold and primary balancing criteria identified in the NCP (40 *CFR* 300.430) and DFF&O. Following the individual analysis, the comparative analysis highlights the key advantages, disadvantages, and tradeoffs among the alternatives.

The modifying criterion of community acceptance is not addressed in the detailed analysis because it relies on stakeholder participation and feedback to the Proposed Plan. The Proposed Plan, which documents the evaluation of remedial alternatives and presents the preferred alternative, will be issued for public review and comment subsequent to regulatory agency concurrence. Public comments on the Proposed Plan and any other components of the Administrative Record File will be addressed in the ROD. The state acceptance criterion will be addressed in the Proposed Plan.

9.1 CRITERIA FOR ANALYSIS

The nine CERCLA evaluation criteria are organized into threshold criteria, primary balancing criteria, and modifying criteria. As discussed in this section, NEPA values are also incorporated into this evaluation.

Threshold Criteria

These criteria are the basis for statutory findings that must be documented in the ROD, and the alternatives must meet the following criteria for implementation:

- Overall protection of human health and the environment
- Compliance with ARARs/TBCs or otherwise satisfy conditions for ARAR(s) waiver.

Primary Balancing Criteria

Primary balancing criteria address performance of the remedial alternative and verify that the alternative is realistic. The ability of alternatives to meet these criteria is evaluated in sufficient detail to enable decision makers to understand the significant aspects of each alternative and any uncertainties associated with the evaluation:

- Long-term effectiveness and permanence
- Reduction of contaminant toxicity, mobility, and volume through treatment
- Short-term effectiveness
- Implementability
- Cost.

Modifying Criteria
The viability of the preferred alternative is evaluated on the basis of the two modifying criteria:

- State acceptance
- Community acceptance.

Other Values
The irreversible and irretrievable use of resources is discussed. NEPA values are also evaluated outside of the CERCLA evaluation as an additional consideration. Issues related to sensitive resources such as wetlands, floodplains, T&E species, and cultural resources are primarily evaluated in the ARARs section that addresses the specific regulatory compliance drivers and needs that are associated with the sensitive resource. Therefore, those discussions will stay with the CERCLA criteria specifically through compliance with location-specific ARARs as well as through relevant discussions of environmental impacts under long-term and short-term effectiveness. Issues related to the impact on human welfare, including environmental justice, socioeconomics and land use, and cumulative impacts associated with NEPA, are covered under the NEPA values section.

9.1.1 CERCLA Criteria

9.1.1.1 Overall protection of human health and the environment

This evaluation criterion assesses each alternative's ability to protect human health and the environment and comply with project-specific RAOs.

The scope of this criterion is broad and reflects assessments discussed under other evaluation criteria, especially long-term effectiveness and permanence and short-term effectiveness. This criterion addresses how risks associated with each pathway would be eliminated, reduced, or mitigated through treatment, engineering controls, or institutional controls. It also evaluates impacts to the site resulting from implementation of the remedial action.

9.1.1.2 Compliance with ARARs/TBCs

This criterion addresses compliance with federal and state environmental requirements and facility siting requirements that are either legally applicable or relevant and appropriate. In certain cases, regulatory standards that address the proposed action or COCs may not exist. In such cases, nonpromulgated advisories, criteria, or guidance developed by EPA, other federal agencies, or states can be designated as potential requirements or TBCs. Other requirements that do not fall within EPA-established criteria for ARARs include DOE Orders that pertain only to DOE facilities. AEA requirements for management of DOE facility waste are incorporated into DOE Orders and developed under DOE AEA authority. Substantive requirements of DOE Orders serve as TBC requirements that, when specifically incorporated into a ROD, become enforceable standards.

ARARs that significantly impact compliance of an alternative include those related to Ohio's siting criteria for on-property disposal, the CAMU rule, RCRA disposal regulations, and various location-specific ARARs, which set forth the considerations and mitigation strategies that must be taken before the land is disturbed. Other key regulations concern transportation and packaging of various kinds of waste.

If an alternative cannot meet an ARAR, a determination can be made that a waiver may be appropriate if certain conditions are satisfied.

Appendix F contains the location- and action-specific ARARs/TBCs for the alternatives under consideration, along with the identification of any waivers that may be needed.

9.1.1.3 Long-term effectiveness and permanence

This criterion evaluates an alternative's ability to achieve overall reduction in risk to human health and the environment, and to provide sufficient long-term controls and reliability. It considers the degree to which the alternative provides sufficient engineering, operational, and institutional controls; the reliability of those controls to maintain exposures to human and environmental receptors within protective levels; and the uncertainties associated with the alternative over the long term. Long-term effectiveness and permanence is evaluated by examining the following issues:

- Magnitude of residual risk and uncertainties
- Adequacy and reliability of controls
- Long-term environmental impacts.

9.1.1.4 Reduction of toxicity, mobility, or volume through treatment

This criterion reflects the statutory preference for remedial action alternatives to substantially reduce toxicity, mobility, or volume of hazardous substances through treatment. It considers the extent to which alternatives can effectively and permanently fix, transform, or reduce the volume of waste materials and contaminated media. The evaluation also considers the amount of material treated; the magnitude, significance, and irreversibility of the given reduction; and the nature and quantity of treatment residuals.

9.1.1.5 Short-term effectiveness

This criterion addresses the impacts on human health and the environment posed by construction and implementation of the alternative. Potential impacts are examined, as well as appropriate mitigation measures for maintaining protectiveness for the community, workers, environmental receptors, and potentially sensitive resources. A major differentiator between the action alternatives is the distance required to transport the wastes. Therefore, a risk of accidents during transport is assessed. Short-term effectiveness is evaluated by examining the following issues:

- Protection of the community during remedial action
- Protection of the workers during remedial action
- Short-term environmental impacts
- Duration of remedial activities.

9.1.1.6 Implementability

This criterion examines the technical and administrative factors affecting implementation of an alternative and consists of three components:

- Administrative feasibility
- Technical feasibility
- Availability of services and materials.

Administrative feasibility addresses the need for coordination with other offices and agencies, including, for off-Site activities, the ability to obtain permits and regulatory agency approvals. Technical feasibility considers difficulties and uncertainties associated with construction and operation of a given technology, the reliability of the technology, the ease of undertaking additional future remedial actions, the ability to monitor effectiveness of remedial action, and the potential risk of exposure from an undetected release. Evaluation of the availability of services and materials includes consideration of the availability of necessary facilities, equipment, technologies, and specialists, and the effect of reasonable deviations on implementability. Especially important are the treatment, storage, and disposal capacities for the waste volumes.

9.1.1.7 Costs

Cost estimates developed to support the detailed analysis are based on feasibility-level scoping and are intended to aid in comparisons between alternatives. EPA guidance states that these estimates should have an accuracy of +50 to -30 percent (EPA 1988). The cost estimates for this FS are based on the scopes of work and assumptions provided in the detailed alternative descriptions in Section 8. No direct costs are associated with the no-action alternative. For the on- and off-Site disposal alternatives, the following costs are addressed:

- Capital costs (direct and indirect)
- S&M costs.

Capital costs include those expenditures required to initiate and perform a remedial action, mainly including design and construction costs. Capital costs consist of direct and indirect costs. Direct costs include construction material, labor, and equipment; service equipment; and utilities. Indirect costs include such elements as Title I and Title II engineering, Title III inspection, project integration, project administration, and management. Capital costs also include (1) long-distance transportation costs and fees paid to off-Site disposal facilities and (2) waste handling and placement, facility maintenance, and monitoring during on-Site disposal operations. Capital costs are incurred through shipment of the waste off Site and include capping of an on-Site disposal facility.

S&M costs are long-term costs that would occur after capping of an on-Site disposal facility, including security, maintenance, and monitoring costs. S&M costs for off-Site disposal are assumed to be included in the disposal fees paid to off-Site facilities. The unescalated S&M costs are presented as an annual cost for two phases, one when an active leachate treatment system is operational and one afterwards when the treatment system is converted to a passive system. Although a time frame for each phase is assumed for a present value calculation, these S&M costs are not added or escalated because any time limit is arbitrary. The annual costs give the decision makers the information they need without biasing the outcome with inaccurate schedule assumptions.

EPA (2000) suggests developing a site-specific period of analysis. For the purposes of this FS alternatives evaluation, a 1,000-year period is used for a present value analysis in the cost estimate to include all capital expenditures in all alternatives as well as the period of time that performance of a potential OSDC was evaluated. However, S&M for both alternatives would continue indefinitely after capping.

Capital costs are estimated as FY 2013 dollars. Project costs are discounted at 2 percent (Office of Management and Budget [OMB] 2010) to develop the present worth costs. No contingency costs are included.

9.1.1.8 State acceptance

This criterion measures the extent to which the State of Ohio through the Ohio EPA supports the proposed alternative being considered for remediation. This modifying criterion will be addressed in the Proposed Plan and ROD.

9.1.1.9 Community acceptance

This criterion measures the extent to which the community supports the proposed alternative. Because formal public comments will not be received until after the FS/Proposed Plan has been issued for review, this modifying criterion will be addressed in the Responsiveness Summary and ROD that will be prepared following the public comment period for the Proposed Plan.

9.1.2 Other Criteria

9.1.2.1 Irreversible and irretrievable commitment of resources

A commitment of resources is irreversible when the impact of the action limits the future options for that resource. An irreversible effect is one where the resource cannot be replaced in a reasonable time frame. Evaluation of the use of fuels, construction materials, land, sensitive resources, and other utilities is conducted.

9.1.2.2 NEPA values

As discussed in Section 9.1, most of the environmental NEPA values such as impacts on surface water, air, groundwater, etc. are addressed under the CERCLA criteria. There are unique NEPA values that are evaluated in these NEPA values sections. The first is the impact of an alternative on human welfare through an evaluation of environmental justice and socioeconomic impacts. This evaluation includes a discussion of jobs.

The Council on Environmental Quality (CEQ) regulations that implement the procedural provisions of NEPA define cumulative impacts as the “impact on the environment which results from the incremental impact of the action when added to past, present, and reasonably foreseeable future actions regardless of what agency (federal or nonfederal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.” (40 *CFR* 1508.7). The cumulative impacts analysis in this section is based on both the potential outcome of a D&D decision under the DFF&O for the PORTS buildings and each of the alternatives in this decision, as well as impacts from historical operations and the potential construction of several new industrial parks in the area.

9.2 INDIVIDUAL ANALYSIS OF ALTERNATIVES

The individual analysis evaluates each of the alternatives with respect to each criterion. The major differences between the alternatives are the disposal location of the generated waste. The no-action alternative has no disposal, Alternative 2 has a mixture of on-Site and off-Site disposal, and Alternative 3 has only off-Site disposal. Common to both action alternatives is the commitment by DOE to recycle and/or reuse waste streams at its discretion. During the development of alternatives (Section 8), a preliminary review of the potential waste streams was conducted to identify the material and volumes that may be candidates for recycling and/or reuse. Roughly 110,000 cy of primarily metals were identified as the representative volume for recycling and/or reuse. Therefore, the disposal volumes are reduced by 110,000 cy in each alternative.

ARARs for recycling and/or reuse and supporting facilities have been included in Appendix F, and all recycling and/or reuse ARARs will be met. Short-term effectiveness does take into consideration the reduction of 110,000 cy of waste volume on cell size and cost of off-Site disposal. However, implementability issues associated with the effort to sort and potentially treat material prior to recycling and/or reuse and any costs associated with facilities or preparatory actions would be the same in both action alternatives and therefore are not discriminating features.

9.2.1 Alternative 1 – No Action

Evaluation of the no-action alternative is required under the DFF&O and CERCLA (40 *CFR* 300.430[e][6]) to provide a basis for comparison with the action alternatives. Under the no-action scenario for this FS, a PORTS Site-wide strategy or infrastructure for coordinated waste disposal would not be implemented. Any waste would be left where generated, open to the environment.

9.2.1.1 CERCLA criteria analysis

9.2.1.1.1 Overall protection of human health and the environment

Under no action, there would be no overall protection of human health and the environment. Buildings would be left to degrade, generating waste that would be either left at the point of generation, moved out of the way, or potentially disposed, but not under any approved decision document. Releases to the environment from contaminants currently protected from the weather would occur. There are risks to human health and the environment both from releases of contaminants and from the physical hazards of uncontrolled access to degrading buildings and/or waste not being disposed. The evaluation of threats to human health show unacceptable on-PORTS risks to future industrial workers and future residents from a sudden release of contamination now encased in the process equipment or from gradual releases of contamination over time.

As shown in the streamlined evaluation of threats to human health (Section 5), the modeling effort in the preliminary WAC development activity and existing contaminant data in off-PORTS groundwater indicate that contaminants released to the environment on PORTS only slowly migrate at sufficient concentrations to be detected at levels of concern off PORTS. The greater threat is from future use of the buildings. Radionuclides (uranium isotopes, technetium), PCBs, metals, and asbestos could present a risk to future users of the buildings or PORTS as the buildings degrade.

Soon, the degrading buildings would increase the complexity and extent of future cleanup activities. This alternative would not support timely cleanup or release of portions of PORTS for beneficial use. The RAOs would not be met by the no-action alternative.

9.2.1.1.2 Compliance with ARARs/TBCs

Pursuant to the EPA Office of Solid Waste and Emergency Response (OSWER) document *ARARs Q's and A's: General Policy, RCRA, CWA, SDWA, Post-ROD Information, and Contingent Waivers* (OSWER Directive 9234.2-01FS) (EPA 1991), there are no ARARs for a no-action alternative; ARARs apply only to remedial actions taken under CERCLA. A no-action decision can only be made when no remedial action is necessary to reduce, control, or mitigate exposure because the plant is already protective of human health and the environment. If the no-action alternative meets the protectiveness threshold criteria, then compliance with ARARs is not pertinent to the selection of the no-action alternative.

9.2.1.1.3 Long-term effectiveness and permanence

There would be significant long-term adverse human health and environmental impacts under the no-action alternative.

Magnitude of residual risk and uncertainties. Remaining buildings and waste left across PORTS would cause an unacceptable risk to human health, safety, and the environment. As shown in the evaluation of threats to human health, both the future on-PORTS risks from contaminant exposure and migration and the future on-PORTS physical risks are unacceptable. The condition of the residual waste from building degradation is unknown. It could be moved, it could be left where generated, or it could be disposed. If left open to the environment, contaminants would migrate from waste and be able to migrate through runoff or groundwater flow, contaminating adjacent soil, surface water, or underlying groundwater. With no institutional controls, humans could be exposed to the contaminants by accessing the building or waste, or could be hurt or killed by falling building material or other accidents. The primary routes of exposure would be through incidental ingestion of soil or ingestion of underlying groundwater that had been contaminated. Radionuclides now safely contained in the process equipment are the greatest source of future on-PORTS risk through release to the environment.

Adequacy and reliability of controls. No controls are in place under the no-action alternative; therefore, the adequacy and reliability of controls is not relevant.

Long-term environmental effects. As described above in the magnitude of residual risk and uncertainties, the release of contaminants into the environment is possible under the no-action alternative. Migration of these contaminants into ecological habitat could have detrimental impacts on terrestrial and aquatic populations. Under the no-action alternative, ecological receptors such as birds, bats, and terrestrial biota would be susceptible to exposure from potential contaminants in or immediately adjacent to the buildings. Ecological receptors farther away would be susceptible through contaminant migration via rainwater infiltration into the buildings and subsequent runoff.

9.2.1.1.4 Reduction of toxicity, mobility, or volume through treatment

The no-action alternative has no reduction in toxicity, mobility, and volume of contaminated waste through treatment.

9.2.1.1.5 Short-term effectiveness

There would be short-term risks under the no-action alternative as S&M and security controls cease. Intruders or workers at PORTS who inadvertently access the degrading buildings could be injured or exposed to unacceptable levels of contamination.

9.2.1.1.6 Implementability

The no-action alternative is technically implementable. There are no material or equipment requirements and no resource needs. However, administratively, the cessation of S&M activities and security controls would be against DOE Orders for managing and safeguarding nuclear materials and therefore would not be implementable. The uncontrolled release of contaminants as the buildings degrade could cause storm water discharges that may exceed existing permit limits, causing notices of violation to be issued.

9.2.1.1.7 Cost

No cost would be directly associated with implementing the no-action alternative; however, the contamination of surrounding media resulting from the release of contaminants during building degradation could result in fines and penalties, as well as ultimately higher remediation costs.

9.2.1.2 Other criteria analysis

9.2.1.2.1 Irreversible and irretrievable commitment of resources

Under the no-action alternative, there are no commitments of resources such as land, energy, or materials of construction.

9.2.1.2.2 NEPA values

Socioeconomics and land use. A consequence of the no-action alternative would be the likely negative impact on reindustrialization efforts for the plant. Abandoned buildings and accumulating waste with no disposal outlet would be detrimental to efforts to reuse the plant. The continuing presence of contaminated buildings and facilities and their associated waste at PORTS would limit or preclude future development of PORTS land. Potential new jobs associated with such development would be lost. Eventually, a loss of population would occur as some unemployed workers and their families leave the ROI for new job opportunities. Therefore, implementation of the no-action alternative would likely result in adverse socioeconomic impacts on the population living in the four-county ROI.

No S&M of PORTS buildings and facilities and no waste disposal would occur under the no-action alternative. Consequently, on-PORTS workers that support these activities would no longer be needed. In turn, these direct job losses and the per capita incomes associated with them would likely result in the loss of indirect jobs in the local businesses that provide goods and services to PORTS workers and their families.

Environmental Justice. Under no action, there are no off-Site activities and no direct impact to any disadvantaged populations. There are no environmental justice issues (EO 12898).

Cumulative impacts. A cumulative impacts assessment was conducted in accordance with the guidance in *Considering Cumulative Effects Under the National Environmental Policy Act* (CEQ 1997). The assessment was based on both geographic (spatial) and time (temporal) considerations. The past, present, and reasonably foreseeable future actions considered in the cumulative impacts assessment are as follows:

- PORTS Project (past uranium enrichment and environmental management operations).

- New industrial park projects in the ROI: Sarah James Industrial Park and Gettles Industrial Park (Jackson County); Zahn’s Corner and Pike County Manufacturing Center (Pike County); Gateway Industrial Park (Ross County); and Ohio River Industrial Park, Haverhill Industrial Park, and the 522 Site (Scioto County). These multiple projects were considered collectively as “industrial parks.”

- Process Buildings and Complex Facilities D&D Evaluation Project. This is a separate DOE project devoted to determining the future of the process buildings and complex facilities at PORTS. This project has two alternatives. Alternative 1 is the no-action alternative under which no D&D would occur. Alternative 2 includes demolition of the buildings and man-made structures. For purposes of the cumulative impacts assessment, Alternative 2 was assumed to be selected.

Geographically, all of these actions are located within the four-county ROI for PORTS. Temporally, the PORTS Project is the only past action that was considered. The rest are present and reasonably foreseeable future actions that would coincide with the anticipated duration of the Site-wide Waste Disposition Evaluation Project.

The no-action alternative would have no cumulative impacts or only minimal cumulative impacts involving surface features, surface water hydrology, geology, population and socioeconomics, land use, transportation, ecology, and irreversible and irretrievable commitments of resources. Scioto County is already a nonattainment area for particulate air pollution ($PM_{2.5}$). Particulates and other airborne contaminants from the deterioration of PORTS buildings and facilities would combine with those from industries in the industrial parks and the increased vehicular traffic around both them and PORTS to further diminish local air quality. Contaminants from miscellaneous waste would eventually infiltrate into soil and groundwater, adding to the contamination already present (TCE) from past PORTS operations.

9.2.2 Alternative 2 – On-Site Disposal

The on-Site disposal alternative involves constructing an on-Site, mixed waste disposal facility at PORTS. Wastes not meeting an on-Site disposal facility's WAC would either be treated at PORTS, shipped off Site for treatment and/or disposal, or be stored pending the availability of treatment or disposal options. Some materials would be recycled and/or reused. Section 8.3 presents a detailed description of this alternative. Because a preferred location has not been chosen, analysis of the on-Site disposal option involves evaluating a potential OSDC at Site D, which represents a potential OSDC at any location of similar geology.

9.2.2.1 CERCLA criteria analysis

9.2.2.1.1 Overall protection of human health and the environment

The on-Site disposal alternative would meet risk-based RAOs and protect human health and the environment by placing future generated waste from the DFF&O (RC-1) into an engineered disposal cell, thereby isolating the wastes from the environment. Additional protection, if needed, would be provided indirectly by treatment of waste to meet the WAC for either on- or off-Site disposal facilities. Placement of wastes into an on-Site disposal facility would result in an overall net reduction of risks associated with the building/structure contamination at PORTS. Protection following capping would be maintained by performance-based design requirements for a potential OSDC and institutional controls such as deed restrictions and an Environmental Covenant.

Monitoring of potential migration pathways would allow evaluation of the effectiveness of waste containment and would provide advance warning of any releases so appropriate mitigation measures could be taken. The potential OSDC will be evaluated for 1,000 years. Environmental impacts at the disposal facility location would result from clearing, grading, construction, and operations. Flora and fauna would be impacted by the permanent commitment of land to the disposal facility.

Certain waste streams may be generated before a potential OSDC is operational, may not meet the WAC for an on-Site disposal facility, or be recycled and/or reused. Early waste streams, waste streams above the WAC that are more effectively handled off Site as opposed to treating on Site to meet the WAC, and material to be recycled and/or reused would be transported off Site for final disposition. It is assumed that 110,000 cy of material are recycled and/or reused (not disposed in a potential OSDC) and another 110,000 cy of waste are sent off Site, either to NNSS, a commercial industrial facility, or a commercial mixed waste facility for disposal.

Human-health and environmental exposures from transport of waste, disposal activities, generation and transport of fill, and storage would be maintained ALARA through compliance with ARARs/TBCs, including DOE Orders, and through health and safety plans developed in compliance with 29 *CFR* 1910.120(b)(4). Radiological risks would be minimized through implementation of the current radiological control program. Exposures to workers during excavation of contaminated fill, if implemented, would be controlled through DOE processes and procedures. Transportation risk would be minimized through selection of appropriate transport routes, compliance with DOT requirements, and adherence to project-specific transportation safety, spill prevention, and cleanup plans. These activities would minimize the likelihood of an accident as well as the severity of a release should an accident occur, maintaining exposures ALARA. Risk of a transportation accident causing injury or fatality is small because of the short distances traveled for the higher volumes of construction materials and the relatively lower volumes of material/waste transported long distances. Risks from exposure to gamma radiation during incident-free transport, vehicular accidents, and exposure to contaminants released during accidents are very low (Sections 9.2.2.1.5 and 9.2.3.1.5).

9.2.2.1.2 Compliance with ARARs/TBCs

The on-Site disposal alternative would comply with all but one location- and action-specific ARARs and pertinent TBC guidance, including DOE Orders (no chemical-specific ARARs were identified). A single waiver for the requirement to be 200 ft from any stream, as defined in *OAC* 3745-27-07, is needed. For purposes of this RI/FS, consolidation of DOE wastes for disposal at an on-Site disposal facility is assumed to be an on-Site action within the meaning of the CERCLA definition of "on-site" (40 *CFR* 300.400[e][1]).

Chemical-specific ARARs. Chemical-specific ARARs generally set cleanup or discharge limits for specific hazardous substances or contaminants. Because no specific media would be remediated under this action, no chemical-specific ARARs for contaminant cleanup levels would apply. Discharge or exposure limits for radiation from wastes disposed of at an on-Site facility or from treatment operations are addressed as action-specific ARARs or TBC guidance. NESHAP (40 *CFR* 61.92) standards limit exposure of the public to not more than 10 mrem of radiation per year. DOE Order 458.1 serves as TBC guidance for limiting the release of radionuclides into the environment. An on-Site disposal facility and on-Site treatment operations would meet these standards through control measures used to meet the ARARs/TBCs detailed in Section 8.2.

Location-specific ARARs. Location-specific ARARs/TBCs specify concentrations or impose restrictions on activities on the basis of sensitive resources present at the planned location. Location-specific ARARs/TBCs for this alternative were identified for the two final candidate locations that are being represented by Site D (Appendix F). Location-specific ARARs/TBCs do not include siting requirements associated with location selection and design of the facility; these are addressed under action-specific ARARs/TBCs. Location-specific ARARs associated with wetlands would be triggered for one of the locations, and ARARs for aquatic resources and cultural resources would be triggered for both locations. Two archaeological sites at Site D may require an additional cultural resources survey and potential mitigation measures if they are impacted by proposed waste disposition activities. No sites are anticipated to be impacted by constructing the haul road. DOE is evaluating impacts of the proposed actions for potential adverse effects on sensitive resources and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

Ohio EPA substantive requirements for a Section 401 Water Quality Certification would be triggered by a wetlands alteration, dredging, or debris removal from an aquatic resource, or the potential filling of any pond. In addition, 10 *CFR* 1022 requires that the impacts of any actions taken in wetlands be considered and avoided wherever possible. If an on-Site disposal alternative is chosen as the preferred alternative for waste disposal, a wetlands delineation and assessment would be completed at the selected location, and mitigation would be planned for any impacted wetlands. The wetland assessment would be used to formulate a wetland mitigation plan, if needed. Detailed evaluations of potential impacts on location resources and plans to minimize and mitigate any adverse impacts would be completed before initiation of any action.

Action-specific ARARs. Action-specific ARARs/TBCs for on-Site disposal address construction, operation, capping, and post-operations care of a potential OSDC. The variety of wastes disposed on Site under this alternative would trigger requirements for RCRA solid and hazardous waste, radiological waste, ACMs, and TSCA wastes. Action-specific ARARs include substantive requirements drawn from RCRA, TSCA, the CAA, and Ohio EPA regulations.

The AEA grants DOE authority for control of its nuclear materials and exempts it from licensing requirements under the NRC. DOE Order requirements for disposal of LLW were identified as TBC guidance and included as siting, design, and operating requirements. Cell design would incorporate an engineered barrier to limit radiological releases via any pathway to a maximum of 0.5 pCi/L above background at the facility boundary, including a double liner and leachate collection system to contain wastes and monitor cell performance. The DOE Order requirements include 24-hour security provisions for at least 30 years and prohibit such a facility from being constructed within a 100-year floodplain. A cell would be designed to be protective for 1,000 years as required by DOE Order 435.1-1.

Cell design would also incorporate ARAR requirements for a chemical landfill under TSCA to accommodate wastes containing PCBs at concentrations ≥ 50 ppm. Most TSCA requirements parallel those of RCRA, and in general, compliance with one set of design requirements implies compliance with the other. The conceptual design meets substantive requirements of both RCRA and TSCA regulations.

Other action-specific ARARs/TBCs address management of storm water runoff, fugitive dust emissions, treatment of leachate and decontamination wastewater, staging or treatment of the wastes during operations, waste storage pending disposal, cell capping, and post-operations maintenance and monitoring. These requirements would all be readily met. Appendix F contains a more detailed discussion of ARARs/TBCs for Alternative 2.

Required ARAR Waiver. The Ohio siting criterion under *OAC* 3745-27-07(H)(4)(d), which requires a setback of 200 ft for solid waste placement in a landfill facility from a stream, lake, or wetland, would need to be waived in accordance with the DFF&O and consistent with CERCLA Section 121(d) and 40 *CFR* 300.430(f)(1)(ii)(C)(2) for this on-Site disposal alternative.

Per the DFF&O, ARAR waivers must be specifically identified and be in accordance with the NCP, and must be agreed to by Ohio EPA in writing. Ohio EPA can relay its agreement with a waiver of an ARAR in either its concurrence with an applicable ROD, Action Memorandum, RD/RA Work Plan, Removal Action Work Plan, or a separate written correspondence.

The basis for this ARAR waiver would be the greater risk presented to human health and the environment posed by any attempt to move the footprint of a potential OSDC in any direction, or to place it at an entirely new study area to avoid the small portion of the unnamed intermittent stream in Study Area D that is within 200 ft of the current landfill waste placement footprint. Based upon the extensive engineering analysis and sensitive resource investigation completed as part of this FS, moving the cell footprint to avoid this small intermittent stream could cause even greater potential damage and violate ARARs associated with protecting more extensive and sensitive resources such as drinking water wells, a groundwater aquifer, sensitive resource wetlands, coldwater and exceptional warmwater habitat streams, and human residences, as well as violate ARARs related to federal depth-to-groundwater-table requirements and state property boundary line requirements. These issues are discussed further below and summarized in Table 9.1. Figure 9.1 shows the proximity of the proposed OSDC footprint, as currently designed, to regulated resources.

Table 9.1. Regulatory Waiver Impact of Moving Potential OSDC within Study Area D or to Another Study Area

Siting Requirement	Study Area/Compliance with Requirement			
	Study Area A	Study Area B	Study Area C	Study Area D
Within 1,000 ft of a water supply well or a developed spring unless one or more of the conditions listed in *OAC* 3745-27-07(H)(3)(c)(i) – (iv) is met. [*OAC* 3745-27-07(H)(3)(c)]	1,630 ft	6,110 ft	1,000 ft	1,595 ft
Above an unconsolidated aquifer system capable of sustaining a yield of 100 gpm for a 24-hour period to a well located within 1,000 ft of where solid waste is placed, unless deemed acceptable by Ohio EPA. [*OAC* 3745-27-07(H)(2)(d)]	[a]	[a]	[a]	[a]
Within 200 ft of a wetland [*OAC* 3745-27-07(H)(4)(d)] – distance from wetland is shown.	795 ft	0 – currently violates	1,295 ft	265 ft– if move cell south, may violate
Within 1,000 ft of a stream area designated by Ohio EPA as a coldwater or exceptional warmwater habitat. [*OAC* 3745-27-07(H)(4)(a)]	1,950 ft	570 ft[b]	2,085 ft	1,625 ft
Within 1,000 ft of a residence whose owner has not consented in writing to its location. [*OAC* 3745-27-07(H)(4)(c)]	1,380 ft	4,330 ft	760 ft – currently violates	1,000 ft – if move cell east, will violate
Within 300 ft of the landfill facility's property line, unless deemed acceptable by Ohio EPA. [*OAC* 3745-27-07(H)(4)(b)]	645 ft	3,095 ft	395 ft	At 500 ft; if move cell east, could potentially violate
Chemical waste (TSCA) landfill must be located above the historical high groundwater table; bottom of the landfill liner shall be at least 50 ft above the historical high water table. [40 *CFR* 761.75(b)(3)]	x	x	x[c]	Currently meets; if move cell from current footprint, may not meet

[a] Both Study Areas A and B overlie an unconsolidated aquifer system; the aquifer may or may not be capable of a sustained yield of 100 gpm for a 24-hour period. Study Areas C and D are not capable of a sustained yield of 100 gpm for a 24-hour period.

[b] Little Beaver Creek, which crosses PORTS, is formally classified pursuant to *OAC* 3745-1-09 (Table 9-1) as, among other uses, Warmwater Habitat. However, Ohio EPA's *Biological and Water Quality Study of the Portsmouth Gaseous Diffusion Plant Streams* (2006) states that Little Beaver Creek meets the criteria for warmwater habitat and portions may attain "exceptional warmwater habitat criteria." Only Study Area B lies within 1,000 ft of Little Beaver Creek. If Little Beaver Creek is formally reclassified to Exceptional Warmwater Habitat, then moving the OSDC to Study Area B would violate this siting restriction and impact a sensitive stream.

[c] Only a portion of Study Area C meets this requirement, limiting the size of the cell to 2.4 million cy.

x= does not meet

CFR = Code of Federal Regulations
OAC = Ohio Administrative Code
Ohio EPA = Ohio Environmental Protection Agency
OSDC = on-Site disposal cell
PORTS = Portsmouth Gaseous Diffusion Plant
TSCA = Toxic Substances Control Act of 1976

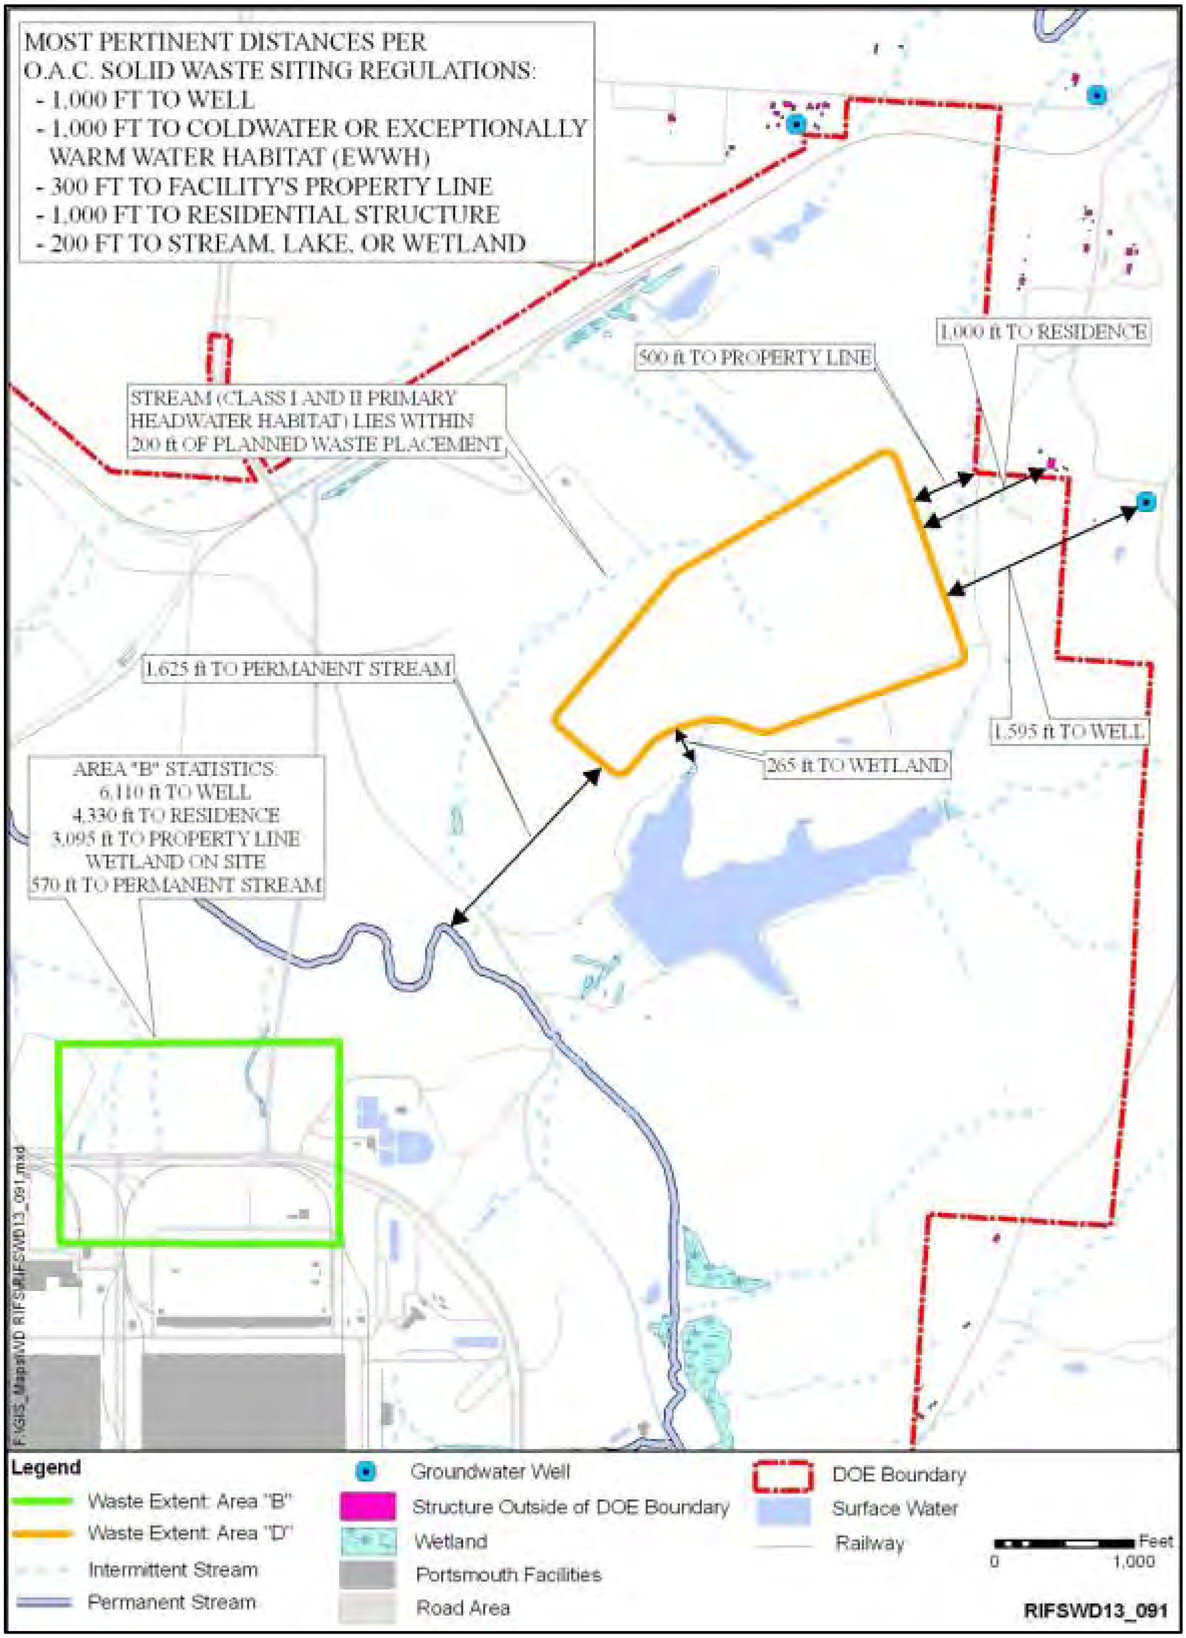


Figure 9.1. Proximity of Potential OSDC Waste Contents to *OAC*-Regulated Items

The Ohio siting requirements in *OAC* 3745-27-07(H)(3)(c) mandate that solid waste placed in a sanitary landfill cannot be placed within 1,000 ft of a water supply well or a developed spring unless one or more of the conditions listed in *OAC* 3745-27-07(H)(3)(c)(i) – (iv) is met. These conditions address situations where a well is used as a nonpotable water source and does not contaminate groundwater or where a hydrogeological barrier of some type can be established to prevent contamination of the well. As currently proposed, the footprint of a potential OSDC in Study Area D is within 1,595 ft of a water supply well. If the footprint is shifted east to avoid the intermittent stream on the location, the project may violate this siting requirement. Locating a potential OSDC at any of the other study areas would allow this ARAR to be met. Potentially contaminating a water supply well is a much greater risk than destroying or potentially contaminating an intermittent stream.

The regional aquifer, the Berea sandstone, is considered to be the “uppermost aquifer system” at Study Area D. The Berea typically has yields greater than 1 gpm and is often the target for installation of residential water supply wells in this area. *OAC* 3745-27-07(H)(2)(d) does not allow solid waste to be placed above an unconsolidated aquifer system capable of sustaining a yield of 100 gpm for a 24-hour period to a well located within 1,000 ft of where solid waste is placed, unless it is deemed acceptable by Ohio EPA. The average yield from the Berea within 1 mile of a potential OSDC at Study Area D is 1.2 gpm. Thus, it is not a sustainable yield subject to this requirement. Both Study Areas A and B overlie an unconsolidated aquifer system; the aquifer, however, may or may not be capable of a sustained yield of 100 gpm for a 24-hour period. Moving a potential OSDC to one of these locations poses the risk of contaminating an aquifer system that could be a potential source of drinking water and violating the ARAR that protects this resource.

Study Area D is within 265 ft of a sensitive wetland, and Study Area B has a wetland within its boundaries. Ohio regulations restrict placement of solid waste within 200 ft of a wetland (*OAC* 3745-27-07[H][4][d]). Study Area B is already in violation of this requirement, and the cell footprint in Study Area D, if moved south to avoid the intermittent stream, would also end up near or on a wetland area, destroying a far more sensitive and delicate resource than a small stretch of intermittent stream.

Ohio restricts the placement of solid waste within 1,000 ft of a stream area designated by Ohio EPA as a coldwater or exceptional warmwater habitat (*OAC* 3745-27-07[H][4][a]). Little Beaver Creek, which flows through PORTS, is formally classified pursuant to *OAC* 3745-1-09 (Table 9-1) as, among other uses, Warmwater Habitat. However, Ohio EPA’s *Biological and Water Quality Study of the Portsmouth Gaseous Diffusion Plant Streams* (2006) and DOE (2013b) state that portions of Little Beaver Creek may attain the “exceptional warmwater habitat criteria.” If Little Beaver Creek is formally reclassified to add the Exceptional Warmwater Habitat designation, then moving the potential OSDC to Study Area B would violate this siting restriction. The risk and ARAR violation this presents would only be encountered if a potential OSDC were relocated to Study Area B, because only Study Area B lies within 1,000 ft of Little Beaver Creek.

As currently sited, the placement of a potential OSDC within Study Area D is 1,000 ft from a residence. *OAC* 3745-27-07(H)(4)(c) mandates that solid waste cannot be placed within 1,000 ft of a residence whose owner has not consented in writing to its location. If the footprint of the cell is moved laterally to the east at all, the distance to this residence will be less than the required 1,000 ft and will be in violation of this requirement. Moving the cell to the proposed location at Study Area C would also be in violation because that location is less than 760 ft from a residence.

If the footprint of the OSDC is moved laterally to the east to avoid the intermittent stream, it may violate the state requirement that mandates the waste placement be at least 300 ft from the facility's property line, unless deemed acceptable by Ohio EPA (*OAC* 3745-27-07[H][4][b]). As currently sited, the facility is 500 ft from the property boundary. Potential locations at the other study areas meet this requirement.

Finally, TSCA requires that a chemical waste landfill must be located above the historical high groundwater table and that the bottom of the landfill liner be at least 50 ft above the historical high water table (40 *CFR* 761.75[b][3]). A potential OSDC, as currently sited, meets this requirement. Study Areas A and B cannot meet this requirement, so moving a cell to these locations would violate a more sensitive ARAR. Only a portion of Study Area C meets this requirement, limiting the amount of PCB-waste that can be disposed to 2.4 million cy.

9.2.2.1.3 Long-term effectiveness and permanence

For the on-Site disposal alternative, the long-term period is considered to begin when all candidate waste has been disposed of and the disposal cell has been covered with a final cap. The alternative also addresses the long-term effectiveness of the off-Site disposal locations used for disposal of a portion of the waste that does not meet the WAC or exceeds the capacity of the cell. This evaluation does not address the waste-generating remedial activities (including treatment under the generating decision document) or waste or residuals that would be left in place at remediation locations.

Magnitude of Residual Risk and Uncertainties

Under this alternative, candidate wastes, treated as appropriate, would be placed in a potential OSDC designed to isolate waste from the environment and significantly reduce the possibility of intrusion into the waste cell or migration of contaminants away from the facility, representing an overall collective decrease in residual risk. By design, meeting the facility WAC would ensure that the total ELCR from the cell would be $< 1\times10^{-5}$, and the total noncarcinogenic risk HI would be less than 1 to future residents living adjacent to the facility, and the underlying groundwater would be protected by ensuring MCLs are not exceeded.

Modeling to support draft modeled WAC selection illustrates that Site D has geologic characteristics that, in concert with the engineering design, do not allow for contaminants at unacceptable levels to migrate from the cell to beyond the waste boundary within a period of 1,000 years, assuming that the facility performs according to projections (DOE 2012a). Because the input parameters used for these calculations were based on the assumption that man-made materials would fail and are likely to overestimate actual future risks from disposed waste, the modeled results are inherently conservative.

Waste not meeting the on-Site disposal facility WAC would either be treated on Site, shipped to off-Site treatment/disposal facilities, or be stored by the generator pending availability of treatment or disposal options. Generally, any treatment would be covered under the generating decision documents. However, if centralized size reduction or decontamination equipment and materials are used, those activities would be part of this alternative and are considered to be effective in the long term for achieving the goals of meeting the WAC or requirements for recycling and/or reuse. Use of the correct equipment would provide the necessary size reduction. Decontamination efforts must be tied specifically to the contamination and waste or material type to be effective, but post-treatment sampling or surveying could be used to assure the goals of the treatment process are met.

If waste is treated or disposed off Site, the receiving facilities would be responsible for monitoring and maintenance to ensure the effectiveness of waste isolation, and acceptable risk levels would be achieved by compliance with existing permits and regulatory requirements. The magnitude of residual risk for off-Site disposal facilities is further addressed in Section 9.2.3.1.3.

Adequacy and Reliability of Controls

Site D of Alternative 2 has sufficient capacity to handle D&D waste (RC-1). As shown in Section 8, the capacity is at least 5 million cy of waste and soil required for disposal of waste, all of which can be disposed over stable bedrock.

The on-Site disposal alternative uses proven technologies to protect human health and the environment and meet risk-based RAOs and ARARs/TBCs. Reliance on proven technologies reduces the uncertainty associated with this alternative. The disposal facilities under this alternative incorporate three types of controls to ensure protectiveness: engineered controls, S&M, and institutional controls.

Engineered controls would be built into a potential OSDC to prevent exposure to contaminants and to prevent, detect, and mitigate contaminant releases. The FML and GCL components of the primary liner would control releases of leachate to groundwater for their design life, which is at least 200 years. The active leachate collection system above the primary liner and the leak detection system below would be effective until the volume of leachate generated is minimal and stable. Long-term control of leachate release would be provided by the secondary liner and geologic buffer and the passive leachate treatment system; these controls would last at least for their design life. An assessment was conducted to estimate the impact on adjacent surface water bodies if the leachate collection or treatment system were to fail and leachate were released directly into the environment. An estimated curie content in the waste in the cell, a TCE mass, and an estimated flow of future leachate (after capping) were used to estimate a concentration of contaminants in the leachate that could be released untreated from a potential OSDC. The entire volume of leachate was then assumed to directly discharge to Little Beaver Creek. Resultant estimated concentrations (see Appendix K for method and results) were significantly below recreational risk-based levels, and no impact to the surface water quality would occur, even under a failure scenario.

The disposal cell cap would prevent airborne releases and direct contact with or exposure to the waste or any contaminated fill. The thickness of the cap (10 ft) and the presence of the biointrusion layer would discourage inadvertent penetration by humans and would prevent or minimize damage from burrowing animals and tree roots. The disposal cell and cap would be designed to remain stable under expected environmental conditions, including possible erosion and earthquakes, for the foreseeable future. Aside from intentional human disturbance or major global climate changes, no credible scenarios for exposing human or ecological receptors to the waste have been identified.

Institutional controls would prevent access to the on-Site disposal facility and use of local groundwater. Institutional controls would continue for an indefinite period, and land use restrictions would be permanent. Monitoring to determine the effectiveness of the primary controls would continue indefinitely.

For those wastes that do not meet on-Site disposal facility WAC and are shipped off Site for disposal, the adequacy and reliability of controls would be acceptable, as discussed for the off-Site disposal alternative (Section 9.2.3.1.3).

Long-term Environmental Effects

For the purpose of this evaluation, long-term environmental effects are those impacts that may occur following capping of a potential OSDC. Long-term protection of ecological receptors from waste in a potential OSDC would be provided by engineered controls, S&M, and institutional controls. Specific components of long-term environmental impacts for the on-Site disposal alternative are addressed in the paragraphs that follow.

Air quality. Air emissions from construction, operation, and capping of the waste cell, centralized treatment, and contaminated fill borrow areas would cease upon completion of cell operation. Because of the generally stable nature of the waste being disposed and administrative requirements forbidding large volumes of biodegradable waste, little degradation is expected within a potential OSDC. The smaller volumes of wood may degrade. The amount of methane gas expected to be generated is considered small. Detailed calculations of the expected volumes of generated gas would be included with the design packages for the cell in order to determine any need for a gas collection system. No long-term impacts to air quality would be expected.

Surface water quality. A potential OSDC would be designed, constructed, and maintained to prevent releases of contaminants or nuisances such as turbidity that could adversely affect surface water quality. Eventually, erosion of the cell could expose waste, resulting in releases to surface water; however, the cell is designed to resist erosion with minimal maintenance, and only extensive erosion would breach containment. S&M of the cap, however, is planned to stop erosions before they could become extensive. Contaminant releases to groundwater from leachate migrating from the cell would be unlikely but could also eventually impact surface water quality. However, calculations presented in Appendix K illustrate that the impacts would be minimal, even under total failure of the leachate collection or treatment system. Fate and transport calculations used to calculate modeled WAC predict that even under conditions where the man-made liners are assumed to fail, the contaminants present in the cell would not reach surface water bodies at unacceptable levels within 1,000 years at either location (see Appendix I).

Any potential OSDC would also be sited in a manner as to minimize impacts to surface water streams. As shown in Section 2, there are no Class III stream segments within 200 ft of the waste disposal location. Construction of a potential OSDC and supporting infrastructure would impact some portion of Class I, Class II, and Class IIIA PHWH streams and some Class I and II stream segments would be permanently displaced. DOE is evaluating impacts of the proposed actions for potential adverse effects to the streams and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

Groundwater quality. Design, construction, and maintenance of a potential OSDC would prevent or minimize contaminant releases to groundwater. These control elements would include a multi-layer cap to minimize infiltration; synthetic and clay barriers in the cell liner, placed on a thick geologic formation; and institutional controls that would include monitoring and groundwater use restrictions. If releases were detected, mitigation measures would be implemented to protect human health and the environment. Long-term impacts to groundwater quality resulting from the implementation of this alternative are expected to be insignificant. Site D is located in ideal geologic conditions to minimize migration potential (Appendix D).

Terrestrial biotic resources. Regardless of the location selected, the land cover at the disposal cell would be altered from a woodland, shrub area with some forests to a grass habitat. Subsequent to cell capping, exposed and disturbed portions of the disposal facility and any borrow areas would be regraded and seeded with native vegetation. Wildlife species displaced by construction and operation activities would, to some degree, begin to occupy these areas again following capping. The species may be different from those originally present. Birds and small mammals in the surrounding area may forage in the disturbed area as the vegetative cover develops. Large mammals would continue to be excluded from the area by the access control fence. Because S&M would continue for an indefinite period, trees would be prevented from growing on the cell cover, but they would probably be allowed to grow between the fence line and the cell, providing a small area of relatively isolated forest habitat. Should S&M lapse, the disposal cell area would eventually progress toward an upland forest, and animals would reoccupy this small area. The biointrusion layer would discourage growth of deep-rooted trees, but would not prevent their establishment over the long term without continued maintenance. The cap integrity could be degraded by uprooting of trees, possibly exposing waste that might impact fauna through contaminant release.

Wetlands and aquatic resources. The potential for impacts to aquatic resources in the vicinity of the disturbed area, primarily the adjacent tributaries, would significantly decrease following capping of the disposal cell and restoration of borrow areas. Sediment retention basins would be removed, and site restoration could include wetland mitigation through restoration or replacement. Surface water would be routed around the waste cell and the impervious cap, and vegetative cover would be maintained indefinitely, increasing the volume of runoff water from the immediate area but preventing sediment loading of adjacent streams. Should S&M lapse, erosion of the cell would likely be minimal because of the relatively gentle slopes of either cell (6:1 side slope and 5 to 10 percent top slope), the riprap erosion protection on the sides, and the vegetative cover on the top. Aquatic resources near either location could be impacted by future contaminant releases from the cell to surface water, should such releases occur. Such releases are considered to be unlikely.

9.2.2.1.4 Reduction of toxicity, mobility, or volume through treatment

Although the on-Site disposal alternative does not directly establish waste treatment requirements, waste generators would generally be required to treat wastes as needed to meet disposal facility WAC before on-Site disposal. For portions of waste disposed off Site, treatment would be applied as needed either before shipment or at the receiving facilities. Solidification or stabilization of waste requiring such treatment would reduce contaminant mobility but could result in a volume increase. Additionally, there may be minor reductions of volumes through centralized size reduction or decontamination efforts at the potential OSDC. A potential OSDC itself would not reduce the mobility, toxicity, or volume of waste through treatment.

The anticipated use of contaminated fill (RC-2, RC-3) may result in the need to treat some of the excavated material to meet WAC at a potential OSDC. Treatment technologies resulting in either volatilization, dewatering, or stabilization of the contaminants likely would be used. Volatilization of contaminants results in a reduction in the volume of contamination, while stabilization results in a reduction of the mobility of the contaminants. Dewatering does not reduce the toxicity, mobility, or volume of contaminants. Any selected treatment system would meet all ARARs.

9.2.2.1.5 Short-term effectiveness

For purposes of this evaluation, “short-term” refers to the period of construction, operation, and capping of a potential OSDC, but does not include the period of post-operations care. This evaluation does not address removal activities, waste, or residuals that would be left in place at the remediation locations, or the risk associated with these elements at individual units being remediated at PORTS.

Protection of the Community during Remedial Action

For Alternative 2, potential risk to the public could result from transportation of hazardous and radioactive waste, operation of a potential OSDC, and windborne dispersion of contaminants. Risk to the public from obtaining fill, waste handling, and disposal activities at PORTS would be low because of the robust and conservative protective systems supporting all phases of operation. Public access would be restricted at on- and off-Site disposal facilities and at all waste generation, packaging, and handling locations. Selection of appropriate transport routes; compliance with DOT packaging and other requirements; and adherence to project-specific transportation safety and spill prevention, control, and countermeasures (SPCC) plans would minimize the likelihood of an accident and the severity of a release should an accident occur.

All waste handling and packaging activities would occur within controlled areas at remediation locations or at a potential OSDC. Most candidate waste streams would present only minor hazards and would be handled in limited quantities; this would ensure that, if a waste handling accident occurred, only minor risk would result. SPCC plans would be prepared and implemented to address any accidents. High-hazard wastes would be managed with additional institutional and physical safeguards. All packaging and handling activities would be conducted in accordance with ARARs/TBCs by trained personnel following an approved health and safety plan. Risks to the public from waste handling and packaging activities would be extremely low.

Vehicles that may impact the public include commuter vehicles and cell construction operation equipment being brought to and from the potential OSDC. During the phases of liner or cap construction at a potential OSDC, the construction would result in an additional 100 to 300 trucks/day on Shyville or Perimeter Road. Such trucks would be bringing rock, other material, or equipment to the construction location.

Waste transportation from PORTS remediation areas to a potential OSDC poses little or no risk to the community from radiation exposure during routine transportation, an increased possibility of vehicular accidents, and exposure to contaminants that might be released during accidents because the transportation would occur on Site. Bypasses would be constructed so on-PORTS worker traffic would have minimal interaction with the on-Site waste transportation efforts.

For cost estimating purposes and to evaluate potential transportation risks only, it is assumed that 26,200 in situ cy of the DFF&O waste generated would not meet an on-Site disposal facility's WAC and would be shipped by truck or rail to Energy*Solutions* in Utah. In addition, 53,000 cy (in situ volume) of PGE (such as converters and compressors) would be shipped by truck to NNSS, and 39,000 cy of solid or construction and demolition debris waste would be shipped to the Pike Sanitation Landfill facility. The risk associated with off-Site waste and construction material transport for both members of the public and transportation workers was assessed to determine the potential number of accidents resulting in injury or fatality. These risks are based on transportation distances from the vendor of construction materials to the construction location and from estimated distances from PORTS to off-Site disposal facilities. The total truck and rail car miles (numbers of trips times distance) are then multiplied by standard rates for truck and rail accidents across the United States (DOE 2002). One caveat to add is that although DOE does not keep separate accident rate statistics that can be used in this context, DOE has greater safety requirements of its drivers, and truck accidents from transporting waste are likely to be lower than those estimated by this method. However, this method is a valid representation of transportation of construction materials or of waste by rail and is sufficient for a comparison of waste transportation by truck by alternative. The risk associated with bringing in construction materials is so small that even an increase in cell capacity would not notably change the total risk of injury or fatality.

The risks of injury or fatality because of a transportation accident are shown in Table 9.2.

Table 9.2. Transportation Risks for Alternative 2

Alternative	Truck Injuries	Truck Fatalities	Rail Injuries	Rail Fatalities
D&D Waste (RC-1)	8.1	0.5	0.1	0.06
Construction materials	0.6	0.02	NA	NA

D&D = decontamination and decommissioning
RC = regulatory category
NA = not applicable

While there is some risk that an accident may happen, packaging requirements are so stringent that the chance of waste material being released during a transportation accident is small. Additionally, the small quantities of waste in a single shipment combined with the short time that any person could be exposed to a spill means that there is no unacceptable risk if an accident were to occur and the load was released from the package.

The potential could exist for community exposure to fugitive dust generated by construction of a potential OSDC and exposure to contaminants from the dispersion of waste by high winds during operation. During construction and operation, fugitive dust generation and other airborne emissions would be monitored. Engineering controls, such as the application of water or chemical dust suppressants and seeding of spoil piles and exposed soils, would be implemented to minimize fugitive dust emissions beyond the facility boundary.

Protection of Workers during Remedial Action

For the on-Site disposal alternative, the primary risks to workers would result from construction and waste handling (including size reduction, decontamination, and fill excavation and treatment), transportation, and disposal activities. These activities would be conducted by trained personnel in accordance with ARARs/TBCs, DOT regulations, DOE requirements, approved health and safety plans, and ALARA principles. The technologies used for size reduction are routinely used at PORTS but do carry risks associated with operating heavy equipment or using manual cutting tools. Decontamination operations may also have some risk through the exposure to contamination or treatment chemicals. Excavation of contaminated fill may increase risks through the excavation of landfills. The excavation of landfills can result in unexpected conditions such as the unearthing or release of previously containerized liquids. However, these risks are mitigated with appropriate project planning, use of PPE, and the use of lessons learned from the excavation of landfills and other activities at Fernald and Oak Ridge for conducting the work. Risk from exposure during disposal activities would be generally limited because the waste would meet a potential OSDC's WAC, which would include components for worker safety (developed during the design). Worker exposure would be further minimized by compliance with DOT and DOE waste packaging, transport, and handling requirements; the use of shielding and PPE; limits on driver work schedules; and other operational restrictions, such as spacing and distancing, to ensure that radiation doses to workers are kept below 5,000 mrem/year. The overall risk to workers for this alternative is low.

Technologies that result in the volatilization of contaminants may be used to treat fill material (RC-2, RC-3) that may not meet the WAC. Air in the area of any treatment system would be monitored for compliance with ARARs and to ensure the protection of workers in the area.

Short-term Environmental Effects

For the purposes of this evaluation, short-term environmental effects are those impacts associated with construction, operation, and capping activities. The short-term period is considered to end upon completion of the installation of the cell cap, projected for completion in FY 2024. For this alternative, the potential for short-term environmental impacts would be posed primarily by construction activities, spills during transportation and handling of wastes or leachate, releases during decontamination operations, impacts during fill excavation, other operational releases, and capping activities. Short-term environmental impacts would be minimized by use of best management practices, including engineered and administrative controls. Specific components of short-term environmental impacts for the on-Site disposal alternative are addressed in the following sections. Short-term impacts for off-Site disposal would be as discussed for Alternative 3.

The short-term environmental risk from transportation would arise primarily from the potential for spills during waste shipment and impacts to air quality resulting from commuter, construction, and operations traffic. Adverse environmental impacts in the event of a spill during waste transport would be minimal because wastes would not be in liquid form, waste volumes per shipment would be small, contaminant concentrations would be low for most waste streams, waste would be properly packaged, and SPCC plans would be quickly implemented if a spill occurred. Safeguards would be implemented to ensure protectiveness during waste transport. Leachate would be conveyed in piping with secondary containment where releases are possible.

Air quality. Potential impacts to air quality would result from exhaust emissions and the generation of particulate matter during construction, operation, and capping of a potential OSDC. Vehicular exhaust emissions would include carbon monoxide, CO_2, sulfur dioxide, and nitrogen dioxide. The peak in traffic would occur during the phases of construction, both of liners and caps, when there would be trucks transporting material, construction worker commuter vehicles, and heavy equipment movement both on Site and off Site. Local air quality could be impacted by vehicular exhaust and fugitive dust associated with the increased traffic required for implementation of the on-Site disposal alternative. Construction and operation of a potential OSDC would not result in a significant increase in the PORTS labor pool (most would just transfer from another PORTS project), so no overall notable increase in commuter traffic or associated increase in pollution would be expected.

With regard to greenhouse gas emissions associated with PORTS, a significant source of CO_2 is employee transportation vehicles. DOE estimated that the 2,700 existing employees on plant resulted in approximately 9,900 tons of CO_2 being emitted annually from employee vehicles (Section 3). In addition, in the 1950s, two coal-fired power generation plants (Kyger Creek in Ohio and Clifty Creek in Indiana) were originally dedicated to supplying electrical power to PORTS. Kyger Creek and Clifty Creek emitted approximately 16 million ton of CO_2 in 2006, based on generating approximately 16.2 million MWh of electricity (SourceWatch 2011a; SourceWatch 2011b; OVEC 2007). This equates to approximately 0.99 ton of CO_2 emitted per MWh. To support current annual electrical requirements at PORTS (approximately 250,000 MWh), approximately 247,500 ton of CO_2 are emitted. This amount, combined with the employee vehicle emissions, means the total existing CO_2 footprint of PORTS is approximately 257,400 ton per year. Appendix K provides calculations to illustrate that truck traffic moving waste and construction materials to a potential OSDC and truck and rail traffic moving waste to off-Site disposal facilities would result in an addition of 53,000 ton of CO_2 emissions over the course of the project. (These calculations do not include the emissions from heavy equipment that would be present at either the on-Site or off-Site disposal facility.) Assuming a 12-year project time frame, the additional CO_2 emissions from building and operating a potential OSDC are approximately 50 percent that of the commuter traffic and less than 2 percent of the total annual carbon footprint of PORTS.

The impacts of exhaust emission from the off-Site transportation of waste not meeting the on-Site disposal facility WAC would also be negligible because the truck loads would be sent over a long period of time (roughly a decade). Requirements for emission controls on the trucks should limit the impact from waste transportation. Impacts on air quality from traffic associated with construction, operation, and capping of a potential OSDC are addressed in the following paragraphs.

A greater potential for impacts to air quality would result from the increase in generation of fugitive dust by earthmoving activities such as during construction, during fill borrow operations, and from traffic on unpaved surfaces or during centralized treatment operations. During construction and operation, there would be significant earthmoving activities at the cell and borrow area. A number of large trucks, including tractor-trailer rigs, large dump trucks, and excavation equipment, would deliver soil and waste daily. The peak level of particulate emissions would be expected during the first 2 years of construction, when the majority of land clearing and fill activities take place. Clearing of land for a potential OSDC and expansion of the PORTS borrow area may result in fugitive dust being visible at facility boundaries. Operations at a borrow area or at an IMTA may release some contaminants into the air, but compliance with ARARs, such as Ohio EPA fugitive dust limits would ensure compliance with federal NAAQS.

Releases from clearing, excavation, construction, and soil removal/hauling would be locally confined at PORTS and would be temporary. Vehicles hauling borrow material would generally be traveling about 5 miles round trip for materials generally available at PORTS. For some materials provided by off-Site commercial vendors, round trip hauling could range between 10 and 200 miles. During construction and operation, fugitive dust generation and other airborne emissions from a potential OSDC would be monitored. Engineering controls, such as the application of water or chemical dust suppressants and seeding of spoil piles and exposed soils, could be implemented to minimize fugitive dust emissions. Particulate matter would be expected to fall out rather quickly because of the relatively large sizes of particles expected to be generated, thereby limiting the area subject to fugitive dust emissions.

Process options to treat potential fill may result in the volatilization of contaminants. Air quality in the vicinity of treatment operations would be monitored. Operating the treatment system in compliance with all air-quality ARARs would result in no unacceptable releases of contaminants to the air.

Surface water resources. A total of 14,335 linear ft of streams (Class I, II, and IIIA) would be directly impacted by construction of a potential OSDC and supporting infrastructure while additional lengths could be indirectly impacted from changes in water quality or quantity. DOE is evaluating impacts of the proposed actions for potential adverse effects to streams and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

To address impacts to streams, the proposed plan would contain proposed mitigation ratios that would be finalized in the ROD. A mitigation plan would be submitted to Ohio EPA during remedial design for approval or concurrence as applicable. Upon closure of the OSDC, much of the area would be recontoured for drainage following removal of requisite infrastructure, except for the area beneath the OSDC footprint.

Potential impacts to surface water resources could result from sediment loading to surface water bodies or migration of contaminants. Land clearing and construction activities would expose varying areas, depending on the location selected and the ultimate size of the facility. The potential impacts to surface water resources would be minimized by using standard erosion controls, such as siltation fences and buffer zones of natural riparian vegetation, during construction activities. Vegetation preserved in the riparian zone (adjacent to the tributaries) would serve as a filter strip for eroded soil, help prevent stream banks from eroding or slumping, and moderate water temperatures through shading. Grass would be planted in cleared areas to minimize the time soils are exposed, stabilize the soils, and control erosion. Some impacts to surface water would be expected.

Surface water runoff from uncontaminated areas of the waste cell would be controlled by sediment detention basins. These basins would prevent increased sediment discharge to the streams and even out discharge during storms. A perimeter ditch would be constructed around the waste cell to prevent surface run-on and direct the water to the sediment basins before release to local streams.

Potentially contaminated runoff from a potential OSDC, water used for decontamination, water from the leachate detection/collection system, contaminated runoff from an IMTA during storage, size reduction, or decontamination efforts, and other wastewater would be collected in storage tanks. This water would be sampled and conveyed to an appropriate treatment facility, as required. The potential for impact to surface water resources from migration of contaminants from a potential OSDC in groundwater would be exceedingly low because of engineered and active controls. Little or no overall short-term impacts to surface water resources would be expected from implementation of this alternative, with the exception of direct impacts to any water courses or wetlands displaced or eliminated by construction.

Potential impacts to surface water would be minimized by only constructing the portions of a potential OSDC that are planned to be used in the immediate future. By not having the entire cell open at one time, the amount of disturbed area would be minimized.

Erosion controls would be needed during any excavation of fill. If contaminated areas are sources of fill such as landfills (RC-3), the excavation during wet weather could result in the spread of contamination to nearby surface water resources if runoff is not controlled. However, the use of berms, vegetation, silt fences, etc. is common, and if weather conditions are not suitable for excavation, it would be halted. Likewise, if the fill were dewatered, the resultant liquid would be controlled and treated or sampled and shown to not exceed ARARs or other discharge requirements before discharge to adjacent surface water bodies.

Groundwater resources. Groundwater resources could be degraded in the short term by a surface spill or disposal cell leachate that migrates to groundwater. Contaminant sources include D&D waste, spills of oil and diesel fuel, releases from transportation or waste handling accidents, and accidental releases of leachate from the disposal cell. Compliance with an approved Erosion and Sedimentation Control Plan and an SPCC Plan would mitigate potential impacts from surface spills. Engineered controls and active controls, including the leachate collection system, would drastically reduce the potential for impact to groundwater resources that could result from contaminant migration from the disposal cell. Implementation of this alternative would result in few or no short-term impacts to groundwater resources.

Terrestrial biotic resources. Impacts to terrestrial biotic resources would result primarily from land clearing that would alter woodlands and shrubs to a disturbed area for the short term, as well as construction and operation activities and controls that would affect the abundance of animals and plant species adjacent to the disposal facility. Construction of a potential OSDC and support areas would require clearing substantial amounts of land. New haul road construction would impact additional land. As a worst-case scenario, this analysis assumes that all of these areas would be cleared within the first year of construction. Alternative construction sequences could be developed to minimize the area exposed at any one time. Clearing of woodlands and shrubs at either of the preferred locations, the haul road, and the PORTS borrow area would increase forest fragmentation. Forest and habitat loss would result, but the presence of surrounding forested areas would somewhat reduce the impact that clearing would have on habitat continuity at these locations. It is unlikely that excavation of fill would have significant impacts to terrestrial biota because most of the likely fill locations are already cleared.

Clearing operations for development of a potential OSDC would cause the direct loss of small animals. Also, many species of wildlife would be displaced from cleared areas and the surrounding forest habitat. Large mammals would be mostly excluded from controlled areas by access control fences. While additional forest-edge habitat would be created, cleared land over the cell would represent a long-term loss of forest habitat. Site clearing would be scheduled during the nonbreeding season of migratory birds to the extent practical to avoid impacting nests and eggs, as required by the Migratory Bird Treaty Act of 1918. Construction and operations activities and the associated noise and human presence would disturb wildlife species occupying habitats adjacent to the selected location. This could result in emigration of some sensitive species from the surrounding area, although many other species could probably adjust. To minimize disturbance to animal habitats, construction machinery would be kept in proper operating condition, and workers would be prevented from entering undisturbed areas delineated before construction.

Specific impacts on the terrestrial biotic communities would include loss of grassland and old-field successional regimes that provide browse and cover, and the loss of mixed hardwood/conifer forest. Forest clearing would directly impact portions of wildlife habitat areas. Various engineering and administrative controls would reduce impacts to these areas. Noise, the loss of adjacent forest habitat, and possibly dust and exhaust emissions may impact adjacent sensitive resources.

Radiation doses received from waste management activities by terrestrial biota would probably be similar to those received by humans. Although acceptable regulatory limits for radiation exposure to species other than humans have not been established, it is generally agreed that the limits established for humans are conservative for animal species. So long as exposure limits protective of humans are not exceeded, no significant radiological impact on biota populations would be expected from waste management activities.

To minimize impacts during construction, roads and utility corridors would be located in existing right-of-ways wherever possible. Areas not immediately required for construction of the waste cell would be seeded to minimize erosion. Following construction of the waste cell, the soil area would be regraded and planted with native vegetation.

Wetlands and aquatic resources. Several wetlands are present within or near the potential facility footprint of Site D (Appendix D). Study Area D including the haul road corridor, has 24 wetlands totaling 4.2 acres (see Figure 2.40). Only one of the wetlands is greater than 1 acre in size. Roughly 0.11 acres would be directly affected with another 2 acres worth of wetlands in Study Area D having the potential for impact during construction activities. There four recently identified wetlands near the haul road, just north of Perimeter Road. They are identified as W01, W02, W03, and W04 from DOE (2013b). There is a chance that these wetlands could be directly affected, depending on the final design of the haul road. Appropriate runoff and siltation controls would be implemented to minimize potential impacts to the wetlands not directly impacted during construction and operation. The fill locations have not yet been selected, and there is the potential that some wetlands may be located near a potential fill area. Before construction or excavation activities are begun, a mitigation plan would be developed.

There are no federal or state radiological standards for aquatic life. However, available evidence indicates that the potential for radiological impacts on such life would be negligible. The concentration of radionuclides released to the environment would not be expected to exceed the radiological limits established for human beings, and research indicates these limits are conservatively applicable for other species.

Of more concern would be impacts on aquatic flora and fauna during construction, operation, and capping of a potential OSDC as a result of sedimentation or oil spills from equipment. Erosion and runoff controls included in the facility design would largely protect aquatic resources from increased turbidity and siltation. Sediment, dust, oil, diesel fuel, gasoline, antifreeze, and other chemicals from construction activities and equipment could enter the aquatic environment if there were a release. Mitigation controls and quick remediation of all spills would minimize the amounts of these materials that are released.

Duration of Remedial Activities

For the on-Site disposal alternative, construction and disposal operations are assumed to continue approximately 10 years (depending on the annual funding). Disposal operations would be followed by a final 1- to 2-year capping period and then post-operations S&M and monitoring. This post-operations care would continue as long as the waste remains a potential threat to human health or the environment. The funding profile assumed was that available in early FY 2012. There is the potential that the schedule for implementing Alternative 2 could increase if annual funding is decreased. The major impact of this schedule extension is to costs and is discussed further in the cost evaluation.

9.2.2.1.6 Implementability

Implementation of Alternative 2 would entail meeting administrative and technical requirements for construction of a potential OSDC; waste packaging, handling, and transport; off-Site transportation and disposal; and interim storage of any waste not meeting the disposal facilities' WAC. This alternative is implementable because the administrative structure required for implementation is largely in place, the required technology is proven, and the services and materials required to implement the action, including an adequate body of vendors, are available.

Administrative Feasibility

The administrative feasibility of Alternative 2 would depend on meeting DOE administrative requirements, continued agreements by regulatory agencies in Utah and Nevada to receive PORTS waste, and possibly agreements by regulatory agencies in several states for the interstate shipment of waste to Utah and Nevada. While administratively feasible, implementation of the on-Site disposal alternative would present administrative challenges, as discussed below.

Under CERCLA 121(e)(1) and paragraph 9.a of the DFF&O, no permitting or licensing would be required for entirely on-Site disposal of DFF&O and CERCLA waste. A potential OSDC would be designed to meet all substantive requirements for a RCRA hazardous waste landfill and a TSCA chemical waste landfill, including associated State of Ohio regulations.

DOE Order 435.1-1 requires that a performance assessment be used to demonstrate that the performance objectives in the Order for disposal of radioactive wastes are met. For CERCLA sites, it is DOE policy to use the CERCLA process to demonstrate attainment of these human health and environmental protection performance objectives in lieu of a performance assessment.

Waste not meeting the on-Site disposal facility WAC would be shipped off Site. A review of state and federal regulations indicates that there are no provisions that would prohibit shipment of waste derived from PORTS to the receiving facilities. These facilities are appropriately licensed and qualified in accordance with 40 *CFR* 300.440, and administrative and substantive regulatory requirements for handling and disposing of waste would be met through compliance with the receiving facilities' permit requirements. The regulatory and administrative viability of off-Site waste transportation and disposal is indicated by past and current operations. Previous PORTS shipments to Energy*Solutions* and NNSS demonstrate that sustained waste shipment to these facilities is feasible.

The off-Site shipment and disposal of waste requires consideration of state equity issues. State equity, with respect to waste management, focuses on the balance of benefits associated with the activities that generate waste and the burden of resulting life cycle waste management activities. The States of Utah and Nevada, as well as those states that shipments would travel through on their way to Utah and Nevada, have historically agreed to the transport and disposal of DOE wastes. It is therefore likely that these governments would be receptive to continued operation. Challenges to the administrative feasibility of this alternative could result from future changes in state acceptance of waste transport and disposal. The administrative feasibility of off-Site disposal, including the issue of state equity, is discussed in greater detail in Section 9.2.3.1.6.

Use of contaminated soil as fill (RC-2, RC-3) may impact areas that have undergone final or interim action under the Ohio Consent Decree. Some of these areas could be landfills that have caps that would be removed if the underlying soil were used as a source of fill. Some of the areas of soil contamination have groundwater interim remedies including monitoring wells and other components in place that may be impacted by fill excavation activities. DOE would be required to seek and gain approval from Ohio EPA before undertaking any fill excavation activities that would impact such interim or final remedies. Completing this process with Ohio EPA would increase the administrative requirements for implementing Alternative 2. Following completion of any fill excavation activities, any follow-on evaluation or remedial activities for the area would be conducted in accordance with the Ohio Consent Decree.

Technical Feasibility

The technical feasibility of Alternative 2 depends on the implementability of waste disposal, treatment, transportation, storage, and supporting activities. The technology currently available for these components is proven and reliable for the waste projected to be generated at PORTS, resulting in a low degree of uncertainty for the implementation of this alternative. However, the construction of a large landfill has many challenges associated with (1) moving large quantities of native materials to prepare the area and install a liner or cap, (2) maintaining quality of the installed materials, and (3) the logistics of placing waste.

The planned design consists of liner construction below grade. This requires the removal and staging of very large quantities of native material. Major earthmoving activities are affected by availability of equipment, location of spoil areas, and the weather. The larger the quantity of material and the shorter the time frame, the more difficult the logistics become. Alternative 2 involves between 2 and 2.5 million cy of native spoils, increasing the difficulty of construction. Moving this material to the spoil area either takes large numbers of equipment pieces or a long time. There also needs to be adequate available space to place this material.

Installation of several liner and cap components must be completed under appropriate weather conditions to ensure their quality. Therefore, these activities are typically scheduled for drier times of the year. Should there be a small schedule delay before the installation, this small delay could result in a year-long delay to the following appropriate construction season. Large volumes of liner and cap materials are required, again adding to the logistical difficulties of coordinating trucks and equipment. Additionally, this installation requires certain expertise to ensure the required end result.

Finally, the actual operation of the cell and placement of the waste involve numerous logistical challenges. To limit subsidence, the waste must be placed and compacted. Material that could degrade must be placed across the cell to avoid differential settling. Soil must be placed around void spaces caused by waste (EC-2) in the cell, so the receipt of that waste (EC-2) at the cell must coincide with soil (EC-1). The large staging area would provide the necessary waste form, but there has to be careful consideration of which waste goes where. Despite these challenges, many segmented disposal cells have been constructed and are operating today, demonstrating their viability. The off-Site shipment and disposal component of the on-Site disposal alternative also represents a reliable, technically robust, and proven method of waste disposal. Off-Site facilities designated for waste not meeting a potential OSDC WAC are already permitted and in operation. Interim waste storage for waste meeting neither the on- nor off-Site disposal facility WAC can also be reliably achieved.

All release pathways at a potential OSDC would be monitored through leachate collection, leak detection monitoring, groundwater monitoring, and physical inspection of external cell conditions. Should releases to groundwater go undetected, groundwater in the immediate vicinity of the cell could be contaminated. The actual risk of exposure from such a release would be low.

Operations anticipated at the potential OSDC involve standard practices associated with heavy equipment operation. Size reduction through heavy equipment attachments or manual cutting has been implemented successfully at PORTS before. Equipment and labor resources are readily available. Decontamination efforts can increase the technical challenges, depending on the technology used. Some are simple such as brushing off contaminated dirt from beams or equipment. Others, such as chemical processes, are more complicated because of the need to collect secondary wastes and possibly handling corrosive or dangerous chemicals. However, these processes are still readily available and can be implemented with little construction activity.

The excavation of fill is technically feasible. If contaminated borrow areas are used, the greatest challenges are associated with excavating the landfills (RC-3). Additional soil would have to be excavated to provide sufficient fill to support placement of waste requiring fill (EC-2) that may be excavated from a landfill into a potential OSDC. An anomaly detection process including visual inspection would need to be put in place to ensure that no unacceptable waste is sent to a potential OSDC. Anomaly detection would slow down excavation efforts. Additionally, monitoring and engineering controls are needed to protect workers from unforeseen conditions, also slowing down production. But there are significant lessons learned from other DOE landfill excavation projects that can be used in planning the work.

For wastes shipped off Site, conditions are well known at the receiving facilities, and potential migration pathways are monitored to detect any contaminant releases and evaluate the effectiveness of waste confinement. Should a release at the Energy*Solutions* or NNSS facility go undetected, the risk of exposure would be small because there are few potential receptors in the vicinity of the facility, and no potable aquifer underlies the facility.

The only significant technical uncertainty relative to this alternative is the availability of treatment and disposal options for waste exceeding the off-Site facilities’ WAC. A technical challenge to implementability could ultimately result if significant volumes of waste were generated and no treatment or disposal options could be identified for them.

Availability of Services and Materials
Services and materials required for potential OSDC construction, off-Site disposal, treatment, storage, and supporting operations would be available for implementation of this alternative. Services and materials required for design, construction, and operation of the disposal cell are readily available, as are qualified personnel, specialists, and vendors. Construction would involve the use of standard construction equipment, trades, and materials. Many companies have successfully constructed disposal cells, and multiple bids could be expected for the procurements necessary to develop a potential OSDC. Landfill construction would occur in phases at either of the two locations. Only the needed capacity would be constructed. A potential OSDC at Site D can be constructed to a total capacity of 5 million cy while not changing any of the basic design parameters.

Large amounts of construction materials would be needed to build a potential OSDC. Nearly 2 million cy of rock, gravel, and soil are needed to construct a potential OSDC at Site D. There are vendors in the area that could provide this quantity of material in the time frame needed. A potential sand and gravel vendor is located approximately 5 miles from PORTS and runs a large-scale operation. Sand/gravel drainage material required for a potential OSDC base leachate collection system and final capping would be dredged and prepared on PORTS by this company. Initial visits indicate that there would be sufficient material of the necessary quality to meet the requirements of a potential OSDC. This facility would transport the material to the OSDC location.

A potential clay soil supplier is located approximately 10 miles from PORTS. They have a large volume of stockpiled clay soil material, and many thousands of cubic yards of material are still in-place. This clay material has been used in sanitary landfill operations and has met the specification requirements for a landfill base and leachate collection system. Material transportation to PORTS would have to be provided.

Permitted off-Site disposal facilities are available and have sufficient capacity to treat and dispose of the waste volume that is anticipated to exceed the potential on-Site disposal facility WAC. Because waste disposal services could be required for up to 10 years, some uncertainty is associated with the availability of these services for the duration of this alternative for commercial, non-DOE facilities. Issues associated with off-Site disposal are further addressed in Section 8.3.3.

Waste treatment and management facilities and services are available at PORTS, including the administrative infrastructure to support comprehensive waste handling and storage operations. There is also sufficient storage capacity for waste that cannot currently be treated and disposed of either on Site or off Site.

9.2.2.1.7 Cost

Estimated unescalated capital costs for Alternative 2 are $1,019 million (in FY 2013 dollars). Table 9.3 provides a breakdown of total unescalated project costs. Capital costs include those for constructing, operating (including leachate treatment during operation), and closing a potential OSDC, leachate treatment systems, support facilities, and a haul road. These costs include costs of excavating and transporting contaminated fill. Capital costs also include off-Site waste transportation and disposal. S&M costs are those long-term costs associated with maintaining and monitoring a closed landfill.

Table 9.3. Cost Estimates for the On-Site Disposal Alternative at PORTS

Project Cost Item	Cost
UNESCALATED CAPITAL COSTS	
Direct Costs for OSDC:	
Cell Construction	$273,280,000
Infrastructure Construction	$53,660,000
Interim Leachate Treatment System Construction	$4,760,000
Cell Operations	$158,440,000
Waste Transport to Cell	$30,440,000
Off-Site Shipment and Disposal	$154,370,000
Interim Leachate Treatment Operations	$8,490,000
Cell Maintenance during Construction	$1,920,000
Permanent Leachate Treatment System Construction	$740,000
Land Use Controls	$180,000
Total OSDC Direct Cost	**$686,000,000**

Table 9.3. Cost Estimates for the On-Site Disposal Alternative at PORTS (Continued)

Project Cost Item	Cost
UNESCALATED CAPITAL COSTS	
Indirect Costs for OSDC:	
Regulatory documents	$410,000
Predesign studies	$9,150,000
Remedial design	$34,600,000
Total OSDC Indirect Cost	**$44,200,000**
Direct/Indirect Costs for Other:	
Recyclables Staging	$14,530,000
Contaminated Fill (RC-2, RC-3)	$273,990,000
Total Other Direct/Indirect Cost	**$288,500,000**
TOTAL CAPITAL COST	**$1,019,000,000**
S&M COSTS	
Long-term S&M cost—initial annual costs	$670,000
Long-term S&M cost—eventual annual costs	$130,000
Capital Cost (Present Worth)	**$868,000,000**
S&M Cost (Present Worth)	**$14,000,000**
TOTAL PROJECT COST (PRESENT WORTH)	**$882,000,000**

OSDC = on-Site disposal cell
RC = regulatory category
S&M = surveillance and maintenance

The cost estimates are based on the estimating methodology described in Appendix L and the technical scope and assumptions for a potential OSDC conceptual design described in Section 8 and Appendix J. The costs are associated with constructing 3.9 million cy of disposal capacity. Post-operations S&M costs were also estimated, resulting in an initial $670,000 annual cost in FY 2013 dollars for monitoring and maintenance of a potential OSDC, decreasing to $130,000 annually once the passive leachate treatment system is operational. S&M costs associated with the off-Site disposal component of the on-Site disposal alternative are assumed to be included in the off-Site facilities' disposal fees. Included in the costs is the cost to excavate fill (RC-2, RC-3), treat the fill that cannot be disposed in a potential OSDC as is, and disposing of 3,900 cy of waste off Site.

A present value evaluation was performed by assuming a 1,000-year project duration. The 1,000-year duration was selected to account for the performance period assessed for Alternative 2. The total present worth cost for Alternative 2 is $882 million.

The following are additional assumptions that significantly affect total project costs:

- Fill borrow locations evaluated in the cost estimate are contaminated soil areas, including landfills (RC-3) and underlying soil associated with areas of groundwater contamination (RC-2). Any ARAR-compliant treatment costs are included.

- Davis-Bacon regulations regarding local prevailing wage rates would be in effect for all construction and operations.

- Profit, fees, overhead, staff size, and management efforts are based on rates consistent with the current D&D contractor.
- No contingency costs are added to the on-Site disposal alternative cost estimate.
- No costs for long-term storage and eventual disposal of any wastes not meeting the WAC for on-Site or off-Site disposal facilities are included.
- The costs and schedule are dependent on the funding allocated. As the schedule increases for Alternative 2, the total capital costs of the alternative increases because there are routine costs that are required to operate a potential OSDC, regardless of how much waste is disposed.

Additional details on the cost estimates are provided in Appendix L.

9.2.2.2 Other criteria analysis

9.2.2.2.1 Irreversible and irretrievable commitment of resources

There are short-term irreversible and irretrievable commitments associated with constructing and operating a potential OSDC and shipping wastes off Site that do not meet the WAC, including: fuel (5 million gal of diesel for trucks and trains) (Appendix K) and other nonrenewable energy resources; geologic resources such as gravel, rock, and soil (total of 2,500,000 cy); and manufactured cell components (synthetic liner material). In addition, fill is likely to be needed during operations to achieve the appropriate EC-1/EC-2 ratio to control subsidence as there is anticipated to be much more waste requiring fill (EC-2) than soil waste (EC-1) generated. The fill may be clean from on or off the Facility or may be from contaminated sources (RC-2, RC-3) on PORTS. Similar resources would be used at the receiving facility for off-Site disposal of wastes not meeting on-Site disposal facility WAC. Wastes sent to the off-Site facility would represent less than 1 percent of the developed disposal capacity at NNSS or Energy*Solutions*.

A potential OSDC would require a permanent commitment of land at PORTS. To support operation of a potential OSDC, as much as 320 acres may be initially cleared for both a potential OSDC and support areas. This would result in the loss of 160 forested acres out of nearly 1,400 acres on PORTS and associated habitat until a potential OSDC were closed and support areas could be restored to natural conditions. As long as the waste would remain in a potential OSDC, the land commitment would be irretrievable. Likewise, there would be an irreversible loss of habitat for wildlife and biota, including Indiana bat habitat, in the immediate area of a potential OSDC. There may be some impacts to wetlands and historic properties. DOE is evaluating impacts of the proposed actions for potential adverse effects to historic properties and wetlands and is developing potential mitigation measures for any adverse effects where avoidance or minimization is not practicable.

Likewise, clearing efforts during non-nesting seasons for birds and bats should lessen short-term impacts on these wildlife. Because of the engineering efforts and limits on the type of waste that could be placed, there should be no impact on other natural resources such as air, adjacent surface water (including fish), underlying groundwater, or nearby drinking water.

9.2.2.2.2 NEPA values

Socioeconomics and Land Use. EPA review of property value studies found there is no established correlation between property values and the location of a contaminated site. EPA found that most studies are ill-fitted to the task of identifying causal linkages between the price effects they evaluate and the impact of EPA cleanup actions. (See EPA, Superfund “What Does the Evidence Say About Property

Value Studies to Assess the Benefits of the Superfund Program" http://www.epa.gov/superfund/programs/recycle/effects/property.html).

While property price effects from a permanent on-Site disposal action are inconclusive, the short-term period impacts to adjacent land parcels, if any, from construction, operation, or final capping of a potential OSDC would be mitigated to the extent practicable. Noise from heavy equipment can often be heard some distance from a construction area. In addition, there would be noise and potentially dust generated from the transport of construction materials. Efforts would be undertaken to minimize noise during nonworking hours, to control dust through wetting roads and, if needed, covering truck loads, and to limit night-time operation that would require lighting. If night time construction would be needed, noise and lighting surveys would be conducted to assess any impact on off-PORTS residents and if mitigation efforts are appropriate. A visual study is underway to understand from where, if anywhere, in the community a closed OSDC would be visible.

The area of influence of a potential OSDC is the area that would be cleared or otherwise impacted by operations (sediment retention basins) where institutional controls would restrict access during operations or following capping. The cell footprint would be kept permanently cleared, representing a long-term impact on direct use of the land. At Site D, the area of influence is 320 acres in the short-term, with a cell footprint varying from 50 to 66 acres (see Appendix J). Approximately 100 acres of this area would not be available for alternate land uses in the long-term as a result of long-term institutional controls.

The land used for the disposal cell would be cleared and maintained, eliminating any forest cover in these areas. The spoils area would be planted with native vegetation after capping and, if not needed for other purposes, would be allowed to revert to forest. The surface facilities area and any fill borrow areas could be revegetated or allowed to revert to natural cover.

For the off-Site disposal component of the on-Site alternative, disposal of PORTS waste at the receiving facilities would have no long-term impacts to socioeconomics or land use in the vicinity of those locations. These facilities are already operating and are committed for the long term to waste disposal and supporting operations. The incremental increase of waste to these facilities from PORTS would not affect the existing long-term land use commitment, and would have little or no impact on the workforce required for operations and maintenance. No changes in local population or nearby industrial or commercial operations would be expected.

There would be a short-term socioeconomic impact associated with the hiring of workers for construction, operation, and capping of a potential OSDC. The workforce would vary with project phases and would likely come from the existing PORTS labor pool or from the local labor market, resulting in minimal, if any, influx of workers to the area. Likewise, the workers needed for operation of a potential OSDC would be drawn from the local workforce. It is estimated that an average of 209 local jobs from 2015 to 2025 would be needed to implement this alternative. The labor estimates are from the cost estimates for this effort (Appendix L). Some of these workers might come from existing PORTS activities and some might be new hires. There would be a small number of long-term jobs associated with the S&M of a potential capped OSDC.

Environmental Justice. EO 12898, "Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations," requires agencies to identify and address disproportionately high and adverse human health or environmental effects its activities may have on minority and low-income populations. Although current assumptions suggest there would be no high and adverse human health or environmental impacts from constructing a potential OSDC, the actual circumstances would depend on specific choices made at the time of development of a potential OSDC. There is only one census tract near the plant where the minority population exceeds the percentage of minority populations for the state. Census Tract 0022, located in Scioto County, is located immediately south of Census Tract 9522 (location of PORTS) (U.S. Census Bureau 2011). No disproportionate effects on minority populations are anticipated; however, in the event adverse impacts occur, they are likely to have at least as much effect on populations that are in closer proximity to PORTS as on minority residents.

Many of the tracts in the ROI meet the definition of low-income populations, especially the tracts nearest PORTS in Pike County. However, these populations are also scattered among higher income populations. Any impacts that affect the low-income tracts are also likely to affect the higher income populations. Any health and environmental impacts that may occur to low-income populations are not expected to have a disproportionate effect. But no impacts to any populations are anticipated due to limited to no off-PORTS activities other than transportation.

Cumulative Impacts. Alternative 2 would have minimal cumulative impacts involving surface features, meteorology, surface water hydrology, geology, soil, hydrogeology, ecology, and irreversible and irretrievable commitments of resources. The design of a potential OSDC would prevent releases from the waste at unacceptable levels either to air, surface water, or groundwater. DOE processes and procedures as well as Ohio regulations would prevent releases of contamination during operation of a potential OSDC. Although historic activities at PORTS have had releases of contamination to the environment, there would be no additional contribution to this contamination from Alternative 2. The area where a potential OSDC most likely would be constructed, if selected, has not been impacted by historical contamination.

Short-term jobs would be added under Alternative 2, and the improved potential for reindustrialization on PORTS land could combine with the new off-PORTS industrial parks to create more jobs and income in the ROI, which would be beneficial cumulative impacts. Similarly, the remediation of PORTS and appropriate waste management, along with the development of the industrial parks, could collectively give more ROI land the potential for productive use. With regard to transportation, the commuter traffic at PORTS would combine with employment at the new industrial parks to increase peak daily traffic on U.S. Route 23, at the U.S. Route 23/State Route 32 intersection, and on other highways and roads in the ROI. Such cumulative increases in traffic volume at PORTS and in its vicinity could adversely impact road serviceability and driver safety, especially during peak daily traffic hours (early morning and late afternoon rush hours), but the impact would not be significant. The addition of a potential OSDC would not be expected to add to the contamination of environmental media at PORTS as a result of past operations. The additional carbon emissions are minimal compared to the emissions from the electrical power sources needed for current plant operations.

9.2.3 Alternative 3 – Off-Site Disposal

The off-Site disposal alternative involves transporting waste generated by DFF&O activities (RC-1) at PORTS to licensed or permitted off-Site disposal facilities, and disposal of the waste in those facilities. All volumes of waste are estimated to meet an off-Site disposal facility’s WAC. A detailed description of the off-Site disposal alternative is provided in Section 8.3.3.

9.2.3.1 CERCLA criteria analysis

9.2.3.1.1 Overall protection of human health and the environment

This alternative would protect human health and the environment and meet risk-based RAOs by removing D&D wastes (RC-1) generated at PORTS, transporting them off Site, and isolating them from the environment by disposal in engineered facilities. As appropriate, material would be recycled and/or reused.

Human health and the environment would be protected in the vicinity of the receiving facilities by disposing of contaminated material appropriately. Operation of these facilities is not likely to result in exposure to waste or releases to the environment because the facilities are designed, licensed, monitored, and maintained to ensure reliable waste containment. The addition of D&D waste (RC-1) from PORTS to these facilities would be protective because the waste would meet the WAC, which have been shown to be protective.

Worker risks from exposure during handling and preparation for transportation would be maintained to ALARA levels and comply with DOE Orders through implementation of engineering controls and health and safety plans developed in accordance with 29 *CFR* 1910.120(b)(4). The increased risk to transportation workers and the community from moving the waste within PORTS and off PORTS would be minimized by compliance with DOT requirements. The considerable transportation distances required for off-Site disposal would result in an increased potential for accidents that could result in injuries, fatalities, or containment releases. Transportation risks from vehicular accidents are detailed in Section 9.2.3.1.5.

9.2.3.1.2 Compliance with ARARs/TBCs

The actions included in the scope of the off-Site disposal alternative would comply with all ARARs and TBC guidance (identified in Appendix F). There are relatively few ARARs/TBCs for this alternative because there are no chemical- or location-specific ARARs after waste is removed from PORTS.

ARARs/TBCs for this alternative are limited to requirements associated with characterization, management, transportation, and disposal of waste. These requirements include packaging, labeling, recordkeeping, placarding, manifesting, and reporting under DOT and RCRA regulations (49 *CFR* 171-174 and 177; 40 *CFR* 261 through 273); TSCA (40 *CFR* 761); the CAA (40 *CFR* 61 and 82); Ohio EPA regulations; and DOE Orders 435.1-1, 458.1, and 460.1A, *Packaging and Transportation Safety*. As noted, only the substantive requirements apply to the entirely on-Site activities under this alternative (collection and preparation of the waste for off-Site transfer). DOE requirements to characterize and certify wastes before off-Site release would be triggered. Because DOE Order 435.1-1 specifies a preference for on-Site disposal of LLW, shipment to a commercial disposal facility would require an exemption. Similar exemptions have been routinely approved since DOE began using commercial disposal capacity in 1992.

The off-Site facilities used for this alternative would be appropriately licensed and qualified in accordance with 40 *CFR* 300.440, which requires the off-Site transfer of any hazardous substance, pollutant, or contaminant generated during CERCLA response actions to a treatment, storage, or disposal facility. This facility must comply with applicable federal and state laws and be approved by EPA for acceptance of CERCLA waste (see also the “Off-Site Rule” at 40 *CFR* 300.440 *et seq.*). Accordingly, DOE would verify with the appropriate EPA regional contact that any needed off-Site facility is acceptable for receipt of these D&D wastes (RC-1) before transfer; the waste would be required to meet the receiving facilities’ WAC. When wastes are transferred off Site, both administrative and substantive regulatory provisions of all legally applicable laws and regulations would need to be met. Accordingly, requirements for permitting, recordkeeping, assessments, or other nonsubstantive elements would be triggered. Administrative and substantive regulatory requirements would be met through the facility license or permit requirements. The owner/operator of the receiving facility would be responsible for all of its financial, operating, and post-operations requirements, including long-term S&M.

Plans that demonstrate compliance with ARARs will be referenced or included in follow-on design reports and will be submitted to Ohio EPA for review and concurrence.

9.2.3.1.3 Long-term effectiveness and permanence

For the off-Site disposal alternative, the long-term period is considered to begin when all candidate waste has been disposed off Site or, if needed, placed in appropriate storage facilities.

Magnitude of Residual Risk and Uncertainties

No residual risk from candidate waste would remain at PORTS subsequent to off-Site disposal of those wastes. At this time, there are no known waste streams that could not be disposed off Site, although the potential remains that some waste may not meet the off-Site facility WAC. The waste would be placed in off-Site engineered disposal facilities designed to isolate waste from the environment, significantly reducing the possibility of intrusion or the migration of contaminants away from the facility. For the portion of waste requiring treatment to meet facility WAC, the potential for contaminant mobility would be further reduced. The receiving facilities would be responsible for monitoring and maintenance to ensure the effectiveness of waste isolation. Acceptable risk levels would be achieved by compliance with existing licenses, permits, and regulatory requirements.

Different implications for long-term risk are associated with disposal at the representative off-Site disposal facilities. The Energy*Solutions* and NNSS facilities are located in an arid environment at a considerable distance from population centers. Low long-term risk to human health results from their remote location, very low precipitation, and the absence of a potable aquifer below the facilities. The municipal landfill in Pike County is also a representative disposal process option. This landfill is designed to isolate waste from the environment, but is located in a much more humid environment and is generally closer to human receptors. The greater amount of rainfall and proximity to human receptors create an environmental setting more conducive to contaminant mobilization and subsequent exposure than at western locations. However, long-term risk at the Pike Sanitation Landfill is low because of the restriction against disposal of hazardous or radioactive waste and the engineering and institutional controls at the facility.

Adequacy and Reliability of Controls

Under the off-Site disposal option, waste would be placed in licensed or permitted engineered disposal facilities that have been receiving wastes for a number of years and have operated in compliance with their permits and federal, state, and local regulations. Accordingly, reliance on specialized or unproven designs or procedures is not necessary to protect human health and the environment or meet risk-based RAOs over the long term. Reliance on proven technologies minimizes uncertainty associated with this alternative.

As part of the permitting process for disposal facilities, comprehensive studies are conducted to establish WAC based on the local environmental setting, site-specific conditions, and the proposed cell design. The WAC establish the waste types, waste forms, and specific contaminants and concentrations that can be disposed safely. The adequacy and reliability of controls for off-Site disposal would be ensured by meeting the WAC for the receiving facilities.

The containment systems at Energy*Solutions* and NNSS are designed to minimize the infiltration of precipitation that could mobilize contaminants. The arid climate and remote locations of the facilities allow the use of simple, durable designs and materials to effectively isolate the waste. This arid climate also contributes to the long-term reliability of the facilities' engineered features and reduces the required level of maintenance and frequency of repairs. The facilities' remote locations also lessen the chance for intrusion, thereby providing a natural enhancement to the effectiveness of institutional controls such as barriers and other security measures. The engineered and natural features at Energy*Solutions* and NNSS are expected to provide adequate and reliable safeguards over the long term. The total remaining capacity of each facility greatly exceeds the anticipated waste volumes from PORTS.

The Pike Sanitation Landfill, while proven successful over many years of operation, cannot accept LLW or hazardous waste, only solid waste. Most of the waste expected to be generated would require management for its radiological or hazardous waste content. The total landfill capacity is more than adequate to handle the 240,000 cy anticipated to be sent from PORTS.

Long-term Environmental Effects
For purposes of this evaluation, long-term environmental effects are those impacts that may be evident following receipt of the last shipment of waste off Site. Any potential environmental impacts associated with transportation, including air emissions and accidental release, would cease after this period. No long-term impacts to air quality, surface water, biota, wetlands, and aquatic or visual resources are anticipated at PORTS or in its vicinity from implementation of this alternative.

Potential long-term environmental impacts from the presence of PORTS wastes at the off-Site disposal facilities are expected to be minimal. These wastes would represent a relatively small portion of the total waste inventory, and the receiving facilities are designed to minimize long-term environmental impacts. No long-term impacts to air quality are expected from the inclusion of PORTS waste at the receiving facilities because emissions from vehicular use and construction activities for long-term monitoring and maintenance of the off-Site facilities would not increase.

9.2.3.1.4 Reduction of toxicity, mobility, or volume through treatment

Although the off-Site disposal alternative does not directly establish waste treatment requirements, wastes would be treated, as needed, before shipment or at the receiving facilities to meet WAC. The treatment of waste off Site at a disposal facility would result in the reduction of toxicity, mobility, or volume through treatment. The impacts of treating waste before packaging and shipment to off-Site disposal facilities are discussed in the documents for those projects generating waste.

9.2.3.1.5 Short-term effectiveness

Short-term effectiveness for the off-Site disposal alternative is evaluated for the period beginning with transport of the packaged waste at PORTS and ending with disposal of all candidate waste streams at the receiving facilities.

Protection of the Community during Remedial Action
Risk to the public from waste handling activities at PORTS would be extremely low. Public access would be restricted at waste handling locations. Activities would be governed by appropriate regulations and conducted by trained personnel. Risks at the receiving facilities would be controlled by compliance with permit requirements; access restrictions during disposal operations would minimize any impact to the community. For the off-Site disposal alternative, potential risk to the public would result only from shipment of hazardous and radioactive waste.

The risk of accidents from long-distance transportation of radioactive and mixed waste to Energy*Solutions* and NNSS by rail and truck and noncontaminated waste to the Pike Sanitation Landfill facility by truck has been calculated. Table 9.4 shows the risks of injury or fatality because of a transportation accident. The total potential injuries from off-Site transportation are estimated at 18.7 with the total potential fatalities estimated at 2.4. The truck estimates are thought to be estimated high because of the extra safety precautions DOE takes with transportation, which are not represented in the statistics.

Table 9.4. Projected Accident-related Injuries and Fatalities for the Off-Site Disposal Alternative

Transportation Method	Projected Accident-related Injuries	Projected Accident-related Fatalities
Truck to NNSS	15.9	0.9
Rail to Energy*Solutions*	2.8	1.5
Truck to Pike Sanitation Landfill	0.04	0.001

NNSS = Nevada National Security Site

While there is some risk that an accident may happen, packaging requirements are so stringent that the chance of waste material being released during a transportation accident would be small. Additionally, the small quantities of waste in a single shipment combined with the short time that any person could be exposed to a spill means that there would be no unacceptable risk if an accident were to occur and the load were to be released from the package.

Protection of workers during remedial action

The primary risks to workers for the off-Site disposal alternative would result from waste handling, waste transportation, and disposal activities. These activities would be conducted by trained personnel in accordance with ARARs/TBCs, DOT regulations, DOE requirements, approved health and safety plans, and ALARA principles. Radiation exposure would be minimized by compliance with DOT regulations and DOE requirements for waste packaging, as well as the use of shielding and limits on driver work schedules. Risk from disposal activities at the receiving facilities would be minimized by compliance with their permit requirements. The overall risk to workers for this alternative is low.

Local and long-distance transportation risks to truck drivers for this alternative are addressed above.

Short-term environmental effects

For this alternative, the primary short-term environmental risks would result from the potential for spills during transportation and handling. Adverse environmental impacts in the event of a spill would be minimal because wastes would not be in liquid form, waste volumes per shipment would be small, contaminant concentrations would be low for most waste streams, and response plans would be quickly implemented if a spill occurred.

The new facilities needed to support expanded rail shipments would be constructed at PORTS for the off-Site disposal alternative, and no short-term impacts on current or projected PORTS land use are anticipated. Accordingly, local surface water resources, biota, and archaeological resources would not be impacted. Potential environmental impacts on surface water, groundwater, terrestrial, wetlands, aquatic, cultural, and visual resources would exist primarily from the receiving facilities. Because these facilities are already operating and committed to waste disposal, the incremental increase of waste from PORTS would not result in significant additional short-term environmental impacts.

With regard to greenhouse gas emissions associated with PORTS, a significant source of CO_2 is employee transportation vehicles. DOE estimated that the 2,700 existing employees on PORTS resulted in approximately 9,900 ton of CO_2 emitted annually from employee vehicles (Section 3). In addition, to support current annual electrical requirements at PORTS (approximately 250,000 MWh), approximately

247,500 ton of CO_2 are emitted. This amount, combined with the employee vehicle emissions, means the total existing CO_2 footprint of PORTS is approximately 257,400 ton per year. Appendix K provides calculations to illustrate that truck traffic and rail traffic moving waste to off-Site disposal facilities would result in an addition of 91,000 ton of CO_2 emissions over the course of the project. (These calculations do not include the emissions from heavy equipment that would be present at the off-Site disposal facility.) Assuming a 20-year project time frame, the additional CO_2 emissions from building and operating a potential OSDC are roughly 50 percent of the commuter traffic and less than 3 percent of the total annual carbon footprint of PORTS.

Exhaust emissions from waste transportation vehicles would have a negligible impact at PORTS or along transportation corridors used for waste shipment. Waste transportation trucks operate under required emission controls. The use of railroads for transport of the largest volumes of waste would decrease vehicle emissions. Fugitive dust generated by truck travel on dirt or gravel access roads would be minimized by dust control measures at the generator areas, PORTS, and receiving facilities. The increase in noise levels along transportation routes would be inconsequential. Noise levels associated with activities at waste-generating areas and packaging and disposal facilities would be minimized by compliance with health and safety plans, which provide appropriate noise controls at these facilities.

Duration of Remedial Activities

Significant waste generation, transportation, and disposal activities are assumed to occur for 20 years, depending on the volume of material generated and the funding available. The funding profile assumed was that available in early FY 2012. There is the potential that the schedule for implementing Alternative 3 could increase if annual funding is decreased. The major impact of this schedule extension is to costs and is discussed further in the cost evaluation.

9.2.3.1.6 Implementability

This alternative is implementable. It would entail meeting administrative and technical requirements to coordinate the transportation and off-Site disposal of waste, and the continued availability of off-Site disposal capacity.

Administrative Feasibility

Implementation of this alternative would require compliance with state and federal regulations; compliance with licensing, permitting, and DOE administrative requirements; agreements by regulatory agencies in Utah and Nevada to receive waste; and possibly agreements by regulatory agencies in several states for the interstate shipment of waste to Utah and Nevada.

A review of state and federal regulations (addressed in Appendix F) indicates that there are no provisions that would prohibit shipment of waste derived from PORTS to the receiving facilities. These facilities are appropriately licensed or permitted and qualified per 40 *CFR* 300.440, and administrative and substantive regulatory requirements for handling and disposing of waste would be met through compliance with facility permit requirements. Shipment of waste from PORTS would require an exemption from the DOE Order 435.1-1 preference for on-site disposal. Similar exemptions have been routinely approved since DOE began using commercial disposal capacity in 1992.

PORTS has shipped waste to Pike Sanitation Landfill. Past D&D waste from PORTS administration buildings, known to be clean through process knowledge, has been shipped to this landfill. The primary challenge with shipping D&D waste to the local landfill is demonstrating that it does not need to be managed for its radiological and/or hazardous content and that it can be released from controls using the process set forth in DOE Order 458.1.

Agreements between and among states for the shipment and disposal of waste involve the issue of state equity, that is, the balance of benefits associated with activities that generate waste and the burden of resulting lifecycle waste management. Central to state equity issues are the elements of reciprocity, equitable federal allocation of monetary resources, and protection of human health and the environment. For example, stakeholders in Utah, states along the transportation route between Utah and Ohio, and other states that dispose of DOE wastes may assert that Ohio should retain the DOE waste generated from Ohio-based operations. Conversely, Ohio stakeholders may argue that all of this waste should not be disposed of within the state because it was generated by a federal agency, and all states have benefitted directly or indirectly from PORTS operations. It is DOE policy that state equity issues be addressed cooperatively with the states in appropriate public forums, primarily through the National Governors Association.

The regulatory and administrative viability of off-Site waste transportation and disposal is indicated by past and current operations. Previous PORTS shipments to Energy*Solutions* and NNSS demonstrate that sustained waste shipment to these facilities is feasible. The States of Utah and Nevada, as well as states along the transportation route between Ohio and Utah and Nevada, have historically agreed to the transport and disposal of DOE wastes. Therefore, it is likely that these states would not object to continued operations. Challenges to the administrative feasibility of this alternative could result from future changes in state acceptance of waste transport and disposal.

Technical Feasibility
The technical feasibility of the off-Site disposal alternative depends directly on the implementability of waste transportation, waste disposal, and supporting activities. All of these activities are done every day at DOE facilities, including PORTS. Technical feasibility indirectly depends on the implementability of treatment, storage, and other waste generator activities, again performed every day at PORTS. The implementability of the technologies currently available for these components is proven and reliable for most waste projected to be generated at PORTS, resulting in a low degree of uncertainty for the implementation of this alternative. It is expected that this alternative could be implemented without schedule delays resulting from technical complications. The only technical uncertainty relative to this alternative is the availability of treatment and disposal options for waste exceeding the off-Site facilities' WAC. If significant volumes of waste were generated and no treatment or disposal options could be identified for this waste, a technical challenge to implementability could ultimately result. Currently, all waste volumes are estimated to meet an off-Site disposal facility WAC.

Site conditions at the receiving facilities are well known, and potential migration pathways are monitored to detect any contaminant releases and evaluate the effectiveness of waste confinement. Should a release go undetected at the off-Site hazardous waste facilities, the risk of exposure would be slight because there are few potential receptors in the vicinity of the facilities and no potable water aquifers underlie the facilities.

Availability of Services and Materials
Services and materials required for waste transportation, treatment, storage, and disposal, as well as supporting construction activities for implementation of the off-Site disposal alternative, would be readily available. Rail and truck transportation have been used to ship PORTS waste in the past. Treatment services, anticipated to consist primarily of stabilization and solidification, are available at the receiving facilities. Treatment materials such as cement and fly ash would also be readily available. Waste management facilities and services are available at PORTS, including the administrative infrastructure to support comprehensive waste handling and storage operations. Supporting construction activities that may be required would involve the use of standard construction equipment, trades, and materials.

The Energy*Solutions* and NNSS facilities, the representative process options for off-Site disposal, are permitted to treat and dispose of most waste types, forms, and quantities expected to be generated by the remediation of PORTS. Both facilities currently accept comparable waste. Because waste disposal services would be required for only 18 to 20 years, the services currently provided are likely to be available for the duration of this alternative. Several other facilities are available to accept hazardous waste, and some facilities can accept LLW. However, at present, no facilities other than Energy*Solutions* and NNSS can accept mixed wastes. These other facilities can be considered during the design phase of this project to assure capacity and to implement a cost-effective remedy. At least one other mixed waste treatment/disposal facility has been proposed, but it has not received state or federal licenses to accept waste. State equity issues could affect the future availability of disposal services to support the off-Site disposal alternative. Disposal capability would have to be assessed throughout implementation of the alternative to determine the viability of continued cost-effective, reliable, and safe off-Site waste disposal.

9.2.3.1.7 Cost

The estimated total project unescalated capital cost is $1.4 billion in FY 2013 dollars. The present worth cost is $1.1 billion. Table 9.5 provides a breakdown of total project costs.

Table 9.5. Cost Estimates for the Off-Site Disposal Alternative at PORTS

Project Cost Item	Cost
UNESCALATED CAPITAL COSTS	
Direct Costs:	
Infrastructure Construction	$17,620,000
Recyclables Staging	$14,500,000
Off-Site Shipment and Disposal	$1,362,000,000
Total Direct Cost	**$1,394,000,000**
Indirect Costs:	
Regulatory Documents	$190,000
Remedial Design	$2,270,000
Total Indirect Cost	**$2,500,000**
TOTAL CAPITAL COST	**$1,397,000,000**
Capital Cost (Present Worth)	**$1,122,000,000**
S&M Cost (Present Worth)	**$0**
TOTAL PROJECT COST (PRESENT WORTH)	**$1,122,000,000**

S&M = surveillance and maintenance

Off-Site disposal alternative costs are based on the technical scope and assumptions described in Section 8.3. The cost estimates for the off-Site disposal alternative are based on the following additional assumptions:

- Costs for waste transport to Energy*Solutions* are based on rail transport, which is less costly than truck transport, and information received from a local transportation vendor. A 30-day round-trip duration for a unit train with 55 railcars and its associated containers is assumed. Mobilization/ demobilization fees for railcars and containers are assumed to be minimal and are not included. Any costs for capital improvements that could be needed at the truck-to-rail transfer facility or elsewhere are assumed to be included in the transportation fees.

- Disposal fees at Energy*Solutions* are based on FY 2011 contract rates with DOE escalated to FY 2013. Disposal fees consider actual as-shipped waste volumes. Energy*Solutions* disposal fees for certain waste forms are based on the total container volume, including any void space for under-filled containers.

- No contingency costs are added to the off-Site disposal alternative cost estimate.

- Wastes classified as mixed wastes at the generator area are assumed to be subject to mixed waste disposal fees at Energy*Solutions*, which are more than three to five times higher than LLW disposal fees. It is possible that treatment of mixed waste to meet RCRA LDRs could remove the hazardous characteristics of some mixed waste streams and that these wastes could then meet the WAC for LLW disposal at Energy*Solutions*. Therefore, the disposal fees at Energy*Solutions* for some mixed waste streams may be overestimated.

- No costs for long-term storage and eventual disposal of wastes not meeting the WAC for off-Site disposal facilities are included.

- The DOE contribution to long-term S&M costs at the off-Site facilities is assumed to be included in the disposal fee. It is assumed that these fees are used to set up a fund to account for future S&M costs. The contribution of the waste in this alternative to the long-term S&M costs at an off-Site disposal facility cannot be estimated.

- Indirect costs such as project management costs and development of health and safety plans are assumed to be included in vendor transportation and disposal fees, and no additional costs are included for the off-Site disposal alternative.

- The schedule is dependent on the funding allocated. However, there is very little cost dependency on schedule although there are some minor routine costs associated with storing recyclable materials.

Additional details on the cost estimates are provided in Appendix L.

9.2.3.2 Other criteria analysis

9.2.3.2.1 Irreversible and irretrievable commitment of resources

Waste packaging, handling, and transportation activities would require an irreversible and irretrievable commitment of fuel (8 million gal of diesel fuel) and other nonrenewable energy resources. Most of the waste packaging containers would be reused. Treatment of waste to meet receiving facility WAC would also require the commitment of stabilization/solidification agents such as cement and fly ash. An irreversible loss of geologic material such as gravel and borrow material would occur at the off-Site disposal facility.

Implementation of the off-Site disposal alternative would require the irreversible and irretrievable commitment of land at the disposal facilities. Land at the receiving facilities is already dedicated to waste disposal, and the addition of PORTS waste would not alter that level of commitment. Waste from this project would represent less than 10 percent of the total space currently available at Energy*Solutions* or NNSS. There would be no long-term commitment of land at PORTS or in its vicinity. Because of the location of most of the off-Site disposal facilities, there should be little to no impact on other natural resources such as fish, wildlife, biota, air, surface water, groundwater, or a drinking water supply.

9.2.3.2.2 NEPA values

Socioeconomics and Land Use. There would be no direct, long-term socioeconomic impacts to PORTS and its vicinity from activities associated with off-Site transportation of waste under this alternative. Potential long-term socioeconomic benefits could be realized from the potential release or reuse of land resulting from the remediation of PORTS.

Disposal of PORTS waste at the receiving facilities is not expected to have long-term socioeconomic or land use impacts in the vicinity of those facilities. These facilities are already operating and are committed for the long-term to waste disposal and supporting operations. The incremental increase of waste from PORTS in these facilities would not affect the existing long-term land use commitment and would have little or no impact on the workforce required for operation and maintenance. No changes in local population or nearby industrial or commercial operations would be expected.

Based on the cost estimate, approximately 40 local jobs on average from 2014 through 2030 have been estimated to be associated with loading waste onto trucks and railcars at PORTS. However, a large portion of the funds would be distributed to vendors outside of the local community, particularly to the off-Site disposal facilities. Only minimal infrastructure would be constructed for local facilities, and only minor modifications would be required for existing facilities. Because the receiving facilities are already operating, the manpower required to support facility infrastructure is already in place. The incremental increase in waste from PORTS could increase short-term manpower needs at these off-Site facilities.

Potential short-term socioeconomic benefits could be realized from the potential reuse of land resulting from the remediation of PORTS. The overall short-term impact on the local economy, population, or commercial and industrial environment depends on future specific remediation decisions.

Environmental Justice. EO 12898, “Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations,” requires agencies to identify and address disproportionately high and adverse human health or environmental effects its activities may have on minority and low-income populations. Although current assumptions suggest there would be no high and adverse human health or environmental impacts, the actual circumstances would depend on specific choices made at the time of transportation and disposal. There is only one census tract near the plant where the minority population exceeds the percentage of minority populations for the state (U.S. Census Bureau 2011). Census Tract 0022, located in Scioto County, is located immediately south of Census Tract 9522 (location of PORTS). No disproportionate effects on minority populations are anticipated; however, in the event adverse impacts occur, they are likely to have at least as much effect on populations that are in closer proximity to PORTS as on minority residents.

Many of the tracts in the ROI meet the definition of low-income populations, especially the tracts nearest the plant in Pike County. However, these populations are also scattered among higher income populations. Any impacts that affect the low-income tracts are also likely to affect the higher income populations. Any health and environmental impacts that may occur to low-income populations are not expected to have a disproportionate effect. But no impacts to any populations are anticipated due to limited off-Site activities other than transportation.

Cumulative Impacts. Alternative 3 would have minimal cumulative impacts involving surface features, meteorology, surface water hydrology, geology, soil, hydrogeology, ecology, and irreversible and irretrievable commitments of resources. Loading trucks or railcars could result in spills, but careful implementation of DOE processes and procedures, as well as following Ohio regulations, would prevent any contribution of environmental contamination. Once the D&D waste (RC-1) has been removed from

PORTS, there is no mechanism for a long-term impact to the environment at PORTS as a result of D&D waste.

Potential reindustrialization on PORTS land could combine with the new industrial parks to create more jobs and income in the ROI, which could be beneficial cumulative impacts. Similarly, the reuse of land at PORTS and the new industrial parks would collectively put more ROI land into productive use. With regard to transportation, an increase in waste transportation at PORTS would combine with employment at the new industrial parks and employment to support D&D to increase peak daily traffic on U.S. Route 23, at the U.S. Route 23/State Route 32 intersection, and on other highways and roads in the ROI. Such cumulative increases in traffic volume at PORTS and in its vicinity could adversely impact road serviceability and driver safety, especially during peak daily traffic hours (early morning and late afternoon rush hours). The emissions from trucks and trains transporting the waste to other locations would increase the carbon footprint of PORTS by roughly 3 percent.

9.3 COMPARATIVE ANALYSIS OF ALTERNATIVES

This comparative analysis evaluates the relative ability of the alternatives to meet the CERCLA evaluation criteria as well as the other criteria considered in the individual analysis. The no-action alternative is not considered to be protective, a threshold criterion. The on-Site disposal alternative would be less costly than the off-Site alternative, but parts of PORTS would have to be permanently dedicated to waste disposal, resulting in impacts on future land use and the environment. The off-Site disposal alternative would remove the wastes completely from PORTS, but long-distance waste transportation in the short term could result in more accidents and is expensive. Table 9.6 presents a summary of the comparative analysis.

Table 9.6. Comparative Analysis Summary

Evaluation Criteria	No-action Alternative	On-Site Disposal Alternative	Off-Site Disposal Alternative
Overall protection of human health and the environment	Not considered protective. Degrading buildings would release contaminants at levels of concern.	Considered protective. Greater protection in the short term because of decreased transportation risks. Equally protective as off-Site alternative for at least 1,000 years.	Considered protective. Equally protective as on-Site alternative for at least 1,000 years. Off Site could be more protective sometime after 1,000 years because of less rainfall.
Compliance with ARARs/TBCs	No ARARs (per EPA OSWER Directive 9234.2-01/FS-4, there are no ARARs for a no-action alternative).	Needs a waiver from *OAC* 3745-27-07(H)(4)(d). Meets all other ARARs.	Meets all ARARs/TBCs.
Long-term effectiveness and permanence	Not effective at protecting human health or the environment.	Very effective for 1,000 years. Permanent use of land-use restrictions and loss of ecological habitat at disposal cell.	Very effective for long-term. Land use at disposal facilities already committed. Waste volume represents small percentages of facility capacity.

Table 9.6. Comparative Analysis Summary (Continued)

Evaluation Criteria	No-action Alternative	On-Site Disposal Alternative	Off-Site Disposal Alternative
Reduction of toxicity, mobility, or volume through treatment. (Actions do not directly establish waste treatment requirements, but waste generators would be required to treat waste as needed before disposal.)	No reduction of toxicity, mobility, or volume.	Disposal facility would not provide any reduction of toxicity, mobility, or volume. Minor reductions through centralized size reduction or decontamination operations.	Disposal facility would not provide any reduction of toxicity, mobility, or volume except where treatment is used at off-Site disposal location to meet waste acceptance criteria.
Short-term effectiveness	No action means no short-term impacts, so effective in the short-term.	Some transportation risks from import of construction materials and transport of waste to NNSS. Some adverse environmental impacts at the on-Site facility from construction and operations, including fill excavation, but would be controlled by appropriate engineering and construction practices.	Transportation risks would increase significantly for the off-Site alternative over no action and over on-Site disposal. Only minor, incremental environmental impacts would occur at the existing off-Site facilities.
Implementability	No implementation required.	Administrative requirements are considered achievable. Construction, fill excavation, and operations are straightforward and readily implementable. Services and materials are readily available. A significant construction effort is still involved.	Administrative and technical requirements are implementable. Disposal relies on commercial facilities; continued availability is likely but uncertain. State equity issues may interfere with future availability.
Cost	No costs.	Present worth cost is $882 million.	Present worth cost is $1.1 billion.
Other Evaluation Criteria	Impact on adjacent land value from residual contamination. Adds to the historic contamination present.	Long-term commitment of 100 acres of land. Uses large volumes of geologic materials. Some socioeconomic benefit from local jobs.	Uses large volume of fuels. Some socioeconomic benefit from fewer but longer-lasting jobs.

ARAR = applicable or relevant and appropriate requirement
EPA = U.S. Environmental Protection Agency
NNSS = Nevada National Security Site
OAC = Ohio Administrative Code
OSWER = Office of Solid Waste and Emergency Response
TBC = to-be-considered

9.3.1 CERCLA Criteria Analysis

9.3.1.1 Overall protection of human health and environment

The no-action alternative is not considered to be protective. It allows the continued degradation of buildings and the accumulation of waste across the plant. This waste can be a future risk to on-PORTS receptors, both human and ecological. Both of the action alternatives are protective. Extensive engineering controls provide protection of human health and the environment, both in the short term and long term. The off-Site disposal alternative may be more protective over the long term (after at least 1,000 years) because Energy*Solutions* and NNSS, the representative disposal facilities for most wastes, are in an arid environment. Overall long-term protection provided by the on-Site alternative (Alternative 2) is acceptable as shown by the fate and transport modeling performed to evaluate modeled WAC for a potential OSDC and by assessing the impacts if the leachate collection/treatment system failed. The effectiveness of institutional controls in restricting actions always has some long-term uncertainty but is similar between on-Site and off-Site disposal.

Both action alternatives would require local and long-distance transportation of construction material and waste. The construction of a potential OSDC or the significant off-Site transport of waste would increase the probability of normal industrial or transportation accidents. Because of the greater volumes of waste shipped over long distances, transportation risks are greater for the off-Site alternative.

9.3.1.2 Compliance with ARARs/TBCs

No ARARs/TBCs are directly associated with the no-action alternative.

A potential OSDC would be designed to meet all ARARs/TBCs except for the siting requirement in *OAC* 3745-27-07(H)(4)(d). Section 8.2 demonstrated that no location on PORTS suitable for constructing a LLW disposal facility could meet all siting requirements or other ARARs. The representative location, Site D, meets most of them and lessens the impact on the environment. A waiver from the 200-ft distance from a stream is needed to ensure the protectiveness and cost-effectiveness of a potential OSDC. The justification for this waiver was provided in Section 9.2.2.1.2. Based on previous granting of numerous waivers at other locations across the nation, the requirement for such a waiver is considered administratively achievable. Certain location-specific ARARs could require mitigation of adverse impacts, but these impacts and requirements are expected to be minimal, and mitigation should be readily implementable.

The off-Site alternative would comply with all ARARs/TBCs (limited to requirements associated with on-Site activities in connection with the transportation of waste), assuming the disposal facilities are in compliance with their licenses and permits.

9.3.1.3 Long-term effectiveness and permanence

The no-action alternative is not effective at achieving RAOs. All of the action alternatives are very effective at protecting human health and the environment. The off-Site disposal alternative may offer a slightly higher level of long-term protectiveness because the climate and hydrogeology offer the highest potential for permanence of containment. Alternative 3 would remove 100 percent of the curies in the buildings while Alternative 2 would remove a smaller amount, but still the majority of curies, from PORTS by removing those waste streams that do not meet the WAC. On-Site disposal would be protective for at least 1,000 years (modeling indicates beyond 1,000 years) for those curies and other amounts of contaminants disposed. The wetter climate could be considered less protective than the arid off-PORTS climates, but the WAC and cell designs would accommodate the wetter climate.

Preventing exposure to contaminants placed in any disposal cell over the long term depends on the success of engineered barriers and institutional controls. A potential OSDC cover and intrusion barrier would be designed to discourage penetration of the cover by humans, burrowing animals, or tree roots. Institutional controls would restrict access and prohibit actions that could penetrate the cover and expose the waste. The effectiveness of the engineering and institutional controls would decrease after active maintenance ceases and sufficient time passes. However, barring extraordinary efforts to penetrate the cover, it should remain effective for hundreds to thousands of years. While the cover remains in place, migration of contaminants into groundwater and surface water is the only credible pathway for exposure. Modeling indicates that exposures would be within an acceptable risk range at the designated receptor locations downgradient of the disposal cell. This assumes that the disposal cell remains intact, it performs as predicted, and institutional controls adequately prevent unacceptable uses of the disposal location. However, calculations show that even if the leachate collection/treatment system fails, releases of leachate to the adjacent surface water bodies would not cause an unacceptable impact.

The off-Site disposal alternative also relies on institutional controls at the off-Site disposal facilities to prevent inadvertent intrusion. The engineered barriers to intrusion and waste migration at Energy*Solutions* and NNSS are similar to the barriers proposed for a potential OSDC in nature and reliability; therefore, the risk of direct exposure to the waste would be roughly similar for the on- and off-Site alternatives. Energy*Solutions* and NNSS, where most wastes (LLW, TSCA, and mixed wastes) would be disposed of, are in arid environments (far from population centers) that reduce the likelihood of contaminant migration or exposure via groundwater or surface water pathways.

Other than replacement of woodland habitat with grass and shrub habitat at the disposal cell, long-term environmental impacts from the on-Site alternative would be small. For the off-Site alternative, the long-term environmental impacts from the incremental increase in disposal volume at the existing facilities would be negligible.

Land use within the permanent institutional control boundary of a potential OSDC would be restricted. Other areas used during construction and operation could be released after facility capping.

9.3.1.4 Reduction of toxicity, mobility, or volume through treatment

The disposal alternatives evaluated do not directly treat waste, but some credit can be taken for the alternatives to reduce the toxicity, mobility, or volume through potential centralized size reduction or decontamination efforts. Generally, the reduction of toxicity, mobility, or volume for individual waste streams through treatment would be evaluated in project-specific decision documents. Treatment of each waste stream by the waste generator, as required to meet the WAC of the selected disposal facility, would be similar for the on- and off-Site alternatives and would reduce toxicity and mobility of contaminants.

9.3.1.5 Short-term effectiveness

The no-action alternative would present no specific short-term risks to the community or workers. The on-Site disposal alternative presents the greatest challenges to the PORTS area during remediation. Construction and operation of the on-Site disposal facility would present more worker and local community risk and impacts to human health and the environment than off-Site disposal, which does not involve extensive new construction. There would be significant truck traffic transporting construction and fill material to and from the potential OSDC location. Off-Site disposal would generate few local impacts and only minor, incremental impacts at the receiving disposal facility. Off-Site disposal would result in additional risk from long-distance transportation.

Under all the alternatives evaluated, risks to workers and the community from actions at the remediation locations and disposal facilities would be controlled through compliance with regulatory requirements and health and safety plans. Excavating fill borrow locations that contain landfills would increase the need for additional planning and oversight to control potential risk to workers. These risks would be similar and would be comparable to risks for industrial operations.

Short-term environmental impacts would be least for the no-action alternative, minimal for the off-Site disposal alternative, and greatest for the on-Site disposal alternative. Environmental impacts during implementation of the off-Site disposal alternative could result from a spill during transport and handling, but there is a low risk of a spill and only minor adverse impacts would result. Vehicles along the transportation corridor would cause an inconsequential increase in pollution and noise levels. The CO_2 emissions would increase for both alternatives but would be a small percentage of the current PORTS CO_2 emissions. The additional environmental impacts at the receiving off-Site disposal facilities would be negligible, over and above those caused by current and continuing operation of the facilities.

Construction and operation of the on-Site disposal facility would cause local, short-term environmental impacts typically associated with a large construction project. Sensitive human receptors (at residences, churches, and schools) would not be impacted because of the distance from these receptors. Disturbance of terrestrial resources would be expected, with land use resulting in temporary losses of habitat; destruction of small, limited-range animals; and displacement of wildlife adjacent to the construction areas. Direct impacts on wetlands, streams, and cultural resources would be small but present. These impacts would be mitigated in accordance with associated ARARs. No impact is expected to T&E species. A potential for releases to the environment during excavation of contaminated sources of fill would need to be assessed and controlled. As discussed previously, additional assessments of impacts on protected resources, if present, would be performed, and mitigation measures would be identified and implemented in consultation with the appropriate state or federal agencies.

The duration of disposal activities for the on- and off-Site disposal alternatives would be based on potential funding and on the logistics of moving waste. It is assumed to take 10 to 12 years to complete Alternative 2, while off-Site disposal of the same volume of waste is assumed to take 20 years based on the funding profile available in early FY 2012. A decrease in available funding would delay the operations of both alternatives comparably. The major impact from lower funding would be an increase in costs with the costs for Alternative 2 increasing faster than costs for Alternative 3. The cost impacts are discussed further in the Cost Evaluation section.

For all alternatives, the most significant risks to the public would result from waste transportation. Potential risks result from exposure to gamma radiation during normal (accident-free) transportation, exposure to radionuclides during accidents, and physical trauma associated with accidents (regardless of the waste being carried). The risk from exposure to radiation during transportation would be extremely low for both on- and off-Site disposal and is not a discriminating factor between the alternatives. However, because of the increased transportation miles, the risk would be inherently greater for Alternative 3. The additional risk of injury or fatality for the off-Site disposal alternative (over two times the number of potential injuries and a nearly five times higher number of potential fatalities than for Alternative 2) is the result of added transportation miles. Although the accident rate for rail is much less than for truck, the accidents are more serious with more fatalities per accident. The estimated fatalities are 0.55 for Alternative 2 and 2.4 for Alternative 3.

9.3.1.6 Implementability

All of the considered alternatives are implementable. All are administratively and technically feasible, although the on-Site component presents greater technical challenges. Services and materials for either action alternative are readily available, although the continued availability of the off-Site disposal capacity is uncertain.

All alternatives are administratively feasible. Development of a potential OSDC would require cooperation with and support from federal and state regulatory agencies, and must include public involvement. For those wastes exceeding a potential OSDC's WAC, administrative feasibility of off-Site shipment and disposal has been demonstrated by successful past shipments.

The off-Site disposal alternative is also administratively implementable. Agreements with state agencies for interstate shipment of waste, and with the States of Utah and Nevada for disposal of waste, have been made in the past, and future agreements may be obtainable. A DOE exemption from the requirement to dispose of LLW at the generation area or at another DOE facility could also be readily obtained.

The technical components of the on-Site disposal alternative would be straightforward to implement using existing and readily available technologies. Off-Site disposal would also be straightforward to implement.

Once the wastes are disposed of on Site or off Site, the need for additional actions in the future would be extremely unlikely. If required, additional actions would be difficult to implement or verify, and they would be very costly for either disposal alternative. The main difference between the on- and off-Site disposal alternatives is the requirement for construction of a potential OSDC versus the long-distance transport requirements for off-Site disposal. Both are readily implementable, but construction of a potential OSDC is more complex.

Services and materials needed for construction and operation of a potential OSDC, or for shipment and disposal of waste under the off-Site alternative, are readily available. Disposal capacity is available for waste that would not meet on-Site facility WAC, under the on-Site disposal alternative, and would require off-Site disposal. Storage capacity would be available for waste not meeting any facility's WAC. Disposal capacity is currently available at the representative off-Site disposal facilities. While several facilities would be available for the small volume of RCRA/TSCA hazardous waste in the candidate waste streams, Energy*Solutions* and NNSS are the only current facilities available that can accept mixed waste for disposal. Some other facilities could accept LLW, but no contracts are in place between these facilities and DOE-PORTS. In addition, there are other administrative impediments. The continued availability of any current commercial facilities for the duration of waste generation is likely. New commercial mixed waste disposal facilities may be developed.

Because of state equity issues, it is possible that public concerns regarding shipments outside of Ohio could affect the availability of off-Site disposal facilities. These concerns could be addressed through appropriate channels such as the National Governors Association and could affect off-Site transport or disposal of waste. The on-Site disposal alternative provides a greater level of certainty that long-term disposal capacity would be available.

9.3.1.7 Cost

Projected present worth costs for the on-Site disposal alternative are lower than the off-Site alternative costs (Table 9.5). Present worth costs, which were evaluated at 1,000 years to include the performance period assessed, are used for comparison between alternatives. There are no costs for the no-action alternative.

The present worth cost of on-Site disposal is estimated to be $882 million, and the present worth cost of off-Site disposal is estimated to be $1.1 billion. Annual S&M costs are associated with Alternative 2. Because DOE would incur these costs, they have been estimated. There are long-term S&M costs that would exist for the off-Site disposal alternative, but they are already factored into the disposal fee and, as such, cannot be estimated as S&M costs.

If the schedule were doubled, and even tripled, Alternative 2 would remain less expensive than Alternative 3, both with respect to capital costs and to present worth costs. A decision based on cost would remain the same. However, because there are set costs associated with operating a potential OSDC regardless of the quantity of waste received, the less waste that is received in a unit time, the more expensive per cy on-Site disposal would become. Comparable routine costs are insignificant in Alternative 3. If the schedule were increased by four to five times the current assumption, Alternative 3 would become less expensive than Alternative 2.

9.3.2 Other Criteria Analysis

9.3.2.1 Irreversible and irretrievable commitment of resources

Both alternatives use some resources that would be irreversible and irretrievable. A potential OSDC would require the use of nearly 320 acres of land that could not be used for other purposes in the near-term with 100 acres not ever available. Nearly 2.5 million cy of geologic resources would be used in the construction of a potential OSDC, and up to 2.3 million cy of soil may be used in the operation of a cell to provide an appropriate EC-1/EC-2 ratio. If a source of fill is selected that contains additional waste requiring fill (EC-2), the amount of fill would increase. Alternative 2 would require over 5 million gal of fuel for the trucks bringing construction materials on Site and removing some of the waste to off-Site disposal locations. Alternative 3 would require over 8 million gal of diesel fuel to transport the waste off Site.

9.3.2.2 NEPA values

There is the potential for long-term socioeconomic impacts from the presence of a potential OSDC at PORTS. A landfill could render nearby areas, both on the DOE property and off PORTS, less desirable for certain uses, depending on local acceptance. The 320 acres of land dedicated to a potential OSDC and support facilities would be only available for that use in the short-term, with 100 acres not available in the long-term. Removal of all waste from PORTS would not result in any negative long-term socioeconomic impacts.

The socioeconomic impacts in the short-term center around the jobs created by each alternative. Alternative 2 produces more jobs locally but for a shorter period of time (12 years). Based on the cost estimate, Alternative 3 produces fewer jobs locally but for a longer period of time (20 years). Local jobs have a positive impact on the surrounding economy. However, the remediation jobs, regardless of which alternative is selected, would not notably increase the total PORTS jobs over current levels.

Neither alternative has significant cumulative impacts to environmental resources when considered with past operations at PORTS as well as new construction in the area. A potential OSDC would be designed to not release contaminants to the environment at unacceptable levels, so there should be no contribution to on-PORTS contamination. The increased traffic on nearby roads resulting from either alternative is not thought to conflict with increased construction traffic at nearby industrial parks because of the existing light traffic on the roads and the small construction efforts at other locations. However, there may be some impacts to driver safety, especially during peak daily traffic hours.

9.3.3 Summary of Differentiating Criteria

Table 9.5 summarizes the similarities and differences among the alternatives. The no-action alternative is not protective and does not meet that threshold criterion.

For most of the evaluation criteria, the differences between on-Site and off-Site disposal are minor. Three key criteria differentiate between the on-Site and off-Site alternatives: (1) short-term transportation risk, (2) duration, and (3) cost.

The statistically-based number of injuries from an accident is 8.8 for Alternative 2 while the same risk is 18.7 for Alternative 3 (off-Site disposal). The statistically-based number of fatalities would be 0.55 for Alternative 2 and 2.4 for Alternative 3.

Alternative 3 could take almost two times as long to implement as Alternative 2. The logistics of moving the large quantity of waste across the country via railroad is more challenging than moving that amount of waste across PORTS.

The present worth costs for the on- and off-Site disposal alternatives are $0.882 billion and $1.1 billion, respectively.

9.4 EVALUATION OF IMPACTS/IMPLICATIONS OF CO-DISPOSAL OF NON-D&D WASTE (RC-2) FROM FUTURE OHIO CONSENT DECREE ACTIVITIES

Up to an estimated 710,000 cy of non-D&D waste (RC-2) from the clean-up of soils and groundwater may be generated at the Portsmouth GDP. Such potential waste streams are associated with environmental media cleanup activities to be conducted under the Ohio Consent Decree and for which DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste stream in any potential OSDC that might be constructed as a result of the Site-Wide Waste Disposition Evaluation Project. The 710,000 cy is an estimate established for the purposes of conducting a complete and thorough evaluation of the alternatives. The actual volume of any non-D&D waste (RC-2) from future Ohio Consent Decree activities will be determined based on several factors. Although the decision supported by this RI/FS is not making a remediation or disposal decision for the potential RCRA material, it is appropriate to understand the impacts this waste may have on the waste disposition decision and, more specifically the WAC and cell design.

Should authorization to allow such waste to be placed in a potential OSDC be requested by DOE and granted by Ohio EPA, the non-D&D waste (RC-2) may be disposed in a potential OSDC. The WAC for a potential OSDC has considered contaminants that may be present in this non-D&D waste (RC-2), and the conceptual design of a potential OSDC has considered the presence and volume of this contamination to ascertain any potential impacts on the long-term effectiveness, short-term effectiveness, and implementability of Alternative 2. The same degree of long-term effectiveness is achieved even if the non-D&D waste (RC-2) is included because the WAC and design considered the potential presence of this waste. All of the transportation of the non-D&D waste (RC-2) would occur on PORTS, so there is no increase in transportation accidents and no new technology is needed to move more contaminated soil to a potential OSDC. Cost impacts are expected to be minor. The cost may increase slightly from constructing and closing additional capacity at the potential OSDC, as well as loading the additional volume into the cell, but these costs are lessened by the fact that soil disposal requires no size reduction and is easily transported to a potential OSDC. Depending on the volume and when the additional waste is generated, there may be no impact to the size of the potential OSDC, which would reduce any cost increase even further. Regardless, the 5 million cy of cell capacity contemplated in this RI/FS would more than adequately cover the maximum additional volume that might be generated under the Ohio Consent Decree (RC-2).

HIGHLIGHTS OF SECTION 9

- Both alternatives are protective of human health and the environment. A protective cell can be built on Site, and several protective disposal facilities exist off Site.
- Construction of a potential OSDC at Study Area D would require a waiver from *OAC* 3745-27-07(H)(4)(d) (200 ft from stream) and would impact 0.11 acres of wetlands and one archaeological site.
- Off-Site disposal removes most of the waste from the local community, consolidating it out west.
- Transporting waste off Site results in a notable increase in traffic accidents and associated impacts over on-Site disposal.
- Off-Site disposal is considerably more expensive and would take longer than on-Site disposal.
- On-Site disposal requires construction of a new disposal cell with large quantities of materials and a significant construction effort. Cell capacity is available for all waste expected to be generated during the cleanup of PORTS.

NEXT STEP: IDENTIFY THE PREFERRED REMEDY SO THE PROPOSED PLAN CAN BE ISSUED FOR FORMAL PUBLIC COMMENT

10. ANCILLARY BENEFITS OF ALTERNATIVE 2

In addition to the evaluation presented in Sections 1 through 9 of this RI/FS, DOE has analyzed Alternative 2 to determine whether there are ancillary programmatic benefits that might be associated with Alternative 2. DOE's analysis has identified several such ancillary benefits. The first such benefit is the potential ability to dispose on Site of non-D&D waste (RC-2, RC-4), as discussed earlier, that would otherwise require off-Site transport and disposal. For example, if the estimated 710,000 cy of non-D&D soil from the deferred units (RC-2) were required to be disposed off Site, it is estimated that 2.7 injuries and 1.45 fatalities may occur as a result of shipping this waste off Site. Sending 710,000 cy of waste off Site would add approximately $600 million to the cost of Alternative 3 which is currently $1.1 billion.

Another ancillary benefit associated with Alternative 2 would be the excavation and placement of contaminated soils into an engineered disposal facility for use as fill when excavation of such soils might not otherwise be required (e.g., potential excavation of landfills [RC-3] that have been compliantly closed under RCRA).

Finally, use of contaminated fill from areas of groundwater contamination (RC-2) may lower costs of remediating the groundwater and soils in the future, may expedite reaching Ohio Consent Decree cleanup levels, and could remove the need for long-term reliance on maintaining landfill caps, significantly lowering the long-term maintenance costs.

Crosswalk between the DFF&O RI Outline and the Site-wide Waste Disposition Evaluation Project RI/FS Report

DFF&O Requirements for the RI (Outline E-1)	Equivalent Contents of the RI/FS Report
EXECUTIVE SUMMARY	**EXECUTIVE SUMMARY**
1.0 INTRODUCTION	**1.0 INTRODUCTION**
1. PURPOSE OF THE REPORT	**1.1. PURPOSE OF THE REPORT**
2. SITE BACKGROUND	**1.2. SITE BACKGROUND**
1.2.1. Site Description This Section should consist of the information in Sections 3.0 and 3.1 of the Preliminary Evaluation Report (PER), Section 1.1 of the RI/FS Work Plan, and Section 1 of the Sampling Plan for the Site-Wide Waste Disposition Evaluation project regarding the Site background and current Site conditions. (See Outlines A-1, B-1, and C-1, respectively in Appendices A, B, and C to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D)Project).	**1.2.1. Site Description**
1.2.2. Site History This Section should consist of the information in Sections 3.0 and 3.1 of the Preliminary Evaluation Report (PER), Section 1.1 of the RI/FS Work Plan, and Section 1 of the Sampling Plan for the Site-Wide Waste Disposition Evaluation project regarding the Site background and current Site conditions. (See Outlines A-1, B-1, and C-1, respectively in Appendices A, B, and C to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D)Project).	**1.2.2. Site History**
1.2.3. Previous Investigations This Section should consist of the information in Section 3.2 of the Preliminary Evaluation Report (PER), Section 1.2 of the RI/FS Work Plan, and Section 1.2 of the Sampling Plan for the Site-Wide Waste Disposition Evaluation project regarding the Site background and current Site conditions. (See Outlines A-1, B-1, and C-1, respectively in Appendices A, B, and C to the Generic Statement of Work for Remedial Investigations(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D)Project).	**2.1 PREVIOUS INVESTIGATIONS** This information has been moved to Section 2.1 for readability.

Crosswalk between the DFF&O RI Outline and the Sitewide Waste Disposition Evaluation Project RI/FS Report (Continued)

DFF&O Requirements for the RI (Outline E-1)	Equivalent Contents of the RI/FS Report
3. REPORT ORGANIZATION	**1.3. REPORT ORGANIZATION**
2.0 STUDY AREA INVESTIGATION As noted in the RI/FS Work Plan Outline and the Sampling Plan Outline for the Site-Wide Waste Disposition Evaluation Project, it is possible that not all of the field activities included in this Section will be required during the RI/FS and included in the Sampling Plan. For those field activities conducted as part of the RI/FS, relevant information provided in the corresponding section of the RI/FS Work Plan and the Sampling Plan and additional information developed or otherwise gathered during the RI should be included in the RI Report in the appropriate Section. This Section includes field activities conducted during the RI associated with Site characterization, including as appropriate and applicable physical and chemical monitoring of the following: **2.1.1. Surface Features (e.g., topographic mapping, natural and man-made features** **2.1.2. Waste Stream Investigations** **2.1.3. Meteorological Investigations** **2.1.4. Surface-water and Sediment Investigations** **2.1.5. Geological Investigations** **2.1.6. Human Population Surveys** **2.1.7. Interim Technical Memoranda** – related to field investigations as revised in response to Ohio EPA comments, if any, shall be included in an appendix and summarized in this section.	**2.0 STUDY AREA INVESTIGATION** This section has been enhanced to include a summary of relevant previous investigations (required in Section 1) to improve the readability of Section 1. Timing of field work to report did not allow separate submittals of Interim Technical Memoranda. **2.1 PREVIOUS INVESTIGATIONS** **2.1.1 Environmental Restoration** **2.1.2 Waste Disposition Planning** **2.1.3 Existing Study Area Data** **2.2 SITE-WIDE WASTE DISPOSITION INVESTIGATIONS** **2.2.1 Waste Stream Characterization** **2.2.2 Potential On-Site Disposal Study Area Characterization** **2.3 DEVIATIONS FROM THE SAMPLING PLAN** **2.4 QUALITY ASSURANCE/QUALITY CONTROL**
3.0 PHYSICAL CHARACTERISTICS OF THE STUDY AREA As noted in the RI/FS Work Plan Outline and the Sampling Plan Outline for the Site-Wide Waste Disposition Evaluation project, it is possible that not all of the field activities included in this Section will be required during the RI/FS and included in the Sampling Plan. For those field activities conducted as part of the RI/FS, relevant information provided in the corresponding section of the RI/FS Work Plan and the Sampling Plan and additional information developed or otherwise gathered during the RI should be included in the RI Report in the appropriate Section. This section includes the results of field activities conducted during the RI to determine physical characteristics, including as appropriate and applicable the following:	**3.0 PHYSICAL CHARACTERISTICS OF THE STUDY AREA** The origin of this section was the information presented in Section 3 of the PER. This section was enhanced to evaluate both historical information and new information to present an overall evaluation of the physical setting of the areas of interest for this waste disposition decision. More detailed characteristics of the study areas being considered for an OSDC are presented in Appendix D. **3.1 SURFACE FEATURES** **3.2 METEOROLOGY** **3.2.1 Regional Climatology** **3.2.2 Air Quality**

Crosswalk between the DFF&O RI Outline and the Sitewide Waste Disposition Evaluation Project RI/FS Report (Continued)

DFF&O Requirements for the RI (Outline E-1)	Equivalent Contents of the RI/FS Report
3.1.1. Surface Features **3.1.2. Meteorology** **3.1.3. Surface water hydrology** **3.1.4. Geology** **3.1.5 Soils** **3.1.6. Hydrogeology** **3.1.7. Demography and Land use** **3.1.8. Ecology**	**3.3 SURFACE WATER HYDROLOGY** **3.4 GEOLOGY** **3.5 SOIL** **3.6 HYDROGEOLOGY** **3.7 DEMOGRAPHY AND LAND USE** **3.8 ECOLOGY**
4.0 POTENTIAL THREAT TO HUMAN HEALTH, SAFETY AND THE ENVIRONMENT This Section should include a streamlined evaluation of the potential threat to human health, safety and the environment based on the information in Sections 3.3 and 3.4 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation project (See Outline A-1 in Appendix A to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project). See also Section 5 of the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project). In addition to the information from Sections 3.3 and 3.4 of the PER, the RI Report should include any additional information or analysis performed based on the results of the Site Characterization process.	**5.0 POTENTIAL THREAT TO HUMAN HEALTH, SAFETY, AND THE ENVIRONMENT** **5.1 POTENTIAL THREAT TO HUMAN HEALTH** **5.2 POTENTIAL THREAT TO ECOLOGICAL RECEPTORS**
4.1.1. Conclusions	The conclusions are included in the text of the main sections.

Crosswalk between the DFF&O RI Outline and the Sitewide Waste Disposition Evaluation Project RI/FS Report (Continued)

DFF&O Requirements for the RI (Outline E-1)	Equivalent Contents of the RI/FS Report
4.1.2. Data Limitations and Recommendations for Future Work Discuss data uncertainties/limitations and identify a description of any necessary additional investigation activities.	**5.3 RISK ASSESSMENT DATA LIMITATIONS AND RECOMMENDATIONS FOR FUTURE WORK** No additional work is recommended.
4.1.3. Revised Remedial Action Objectives This Section should include the information in Section 4.2 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation project. (See Outline A-1 in Appendix A to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D)Project), along with a discussion of any revisions or refinements to the Remedial Action Objectives set forth in the PER.	**5.4 REVISED RAOS** No refinements were made to the remedial action objectives.
5.0 REFERENCES	**11.0 REFERENCES**
6.0 TABLES AND FIGURES (At least one set of figures shall be no larger than 11” × 17”)	Tables and figures are embedded within the text.
7.0 APPENDICES Include as appropriate and applicable based on activities conducted during the Remedial Investigation. Examples may include: 1. Log Books 2. Soil Boring Logs 3. Test Pit/Trenching Logs 4. Soil Gas Probe Construction Diagrams 5 Monitoring Well Construction Diagrams 6. Sample Collection Logs 7. Private and public Well Records 8. Technical Memoranda on Field Activities 9. Analytical Data and QA/QC Evaluation Results 10. Detailed Modeling Reports	**APPENDIX A: ANALYTICAL SAMPLE RESULTS** **APPENDIX B: BORING AND WELL INSTALLATION LOGS** **APPENDIX C: GEOTECHNICAL AND GEOCHEMICAL SAMPLE RESULTS** **APPENDIX D: CHARACTERISTICS OF FINAL CANDIDATE LOCATIONS** **APPENDIX E: WASTE VOLUMES**

Crosswalk between the DFF&O FS Outline and the RI/FS Report
Site-wide Waste Disposition Evaluation Project

DFF&O Requirements for the FS (Outline G-1)	Equivalent Contents of the RI/FS Report
EXECUTIVE SUMMARY	**EXECUTIVE SUMMARY**
1.0 INTRODUCTION	**1.0 INTRODUCTION**
1.1 PURPOSE AND ORGANIZATION OF THE STUDY	**1.1 PURPOSE OF THE REPORT** **1.3 REPORT ORGANIZATION**
1.2 SITE BACKGROUND SUMMARY	**1.2 SITE BACKGROUND**
1.2.1 Site Description This Section should consist of appropriate information in Section 1.2.1.2.1 and 1.2.1.2.2 of the Remedial Investigation Report for the Site-Wide Waste Disposition Evaluation project (See Outline E-1 in Appendix E to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plan (Decontamination and Decommissioning (D&D) Project).	**1.2.1 Site Description**
1.2.2 Site History This Section should consist of appropriate information in Section 1.2.1.2.1 and 1.2.1.2.2 of the Remedial Investigation Report for the Site-Wide Waste Disposition Evaluation project (See Outline E-1 in Appendix E to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plan (Decontamination and Decommissioning (D&D) Project).	**1.2.2 Site History**
1.2.3 Results of Waste Stream Investigations This Section should consist of information in Section 3.0 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation project (See Outline A-1 in Appendix E to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plan (Decontamination and Decommissioning (D&D) Project), together with any additional information or analysis developed during a Remedial Investigation.	**2.2 SITE-WIDE WASTE DISPOSITION INVESTIGATIONS** This information has been enhanced through additional waste stream investigation data collection. The results are presented in Section 2 as required by Outline E-1.
1.2.4 Environmental Setting This information will only be required if the remedial alternatives being developed for consideration under the Site-Wide Waste Disposition Evaluation project include a potential OSDC. If required, this section should present the information developed during a Remedial Investigation regarding environmental setting.	**3.0 PHYSICAL CHARACTERISTICS OF THE STUDY AREA** An OSDC is under consideration. The environmental setting is described in Section 3, as required by Outline E-1.

Crosswalk between the DFF&O FS Outline and the RI/FS Report Sitewide Waste Disposition Evaluation Project (Continued)

DFF&O Requirements for the FS (Outline G-1)	Equivalent Contents of the RI/FS Report
1.2.5 Summary of Threat to Human Health, Safety and the Environment This Section should consist of a streamlined evaluation of the potential threat to human health, safety and the environment based on information in Section 4.0 of the Remedial Investigation Report for the Site-Wide Waste Disposition Evaluation projects (See Outline E-1 in Appendix E to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project), together with any additional information or analysis developed during a Remedial Investigation.	**5.0 POTENTIAL THREAT TO HUMAN HEALTH, SAFETY, AND THE ENVIRONMENT** The threat to human health, safety, and the environment is presented in Section 5, as required by Outline E-1.
1.3 BASIS FOR PROJECTED WASTE STREAMS AND VOLUMES AND POTENTIAL UNCERTAINTIES This Section should consist of information in Section 3.0 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation projects (See Outline A-1 in Appendix A to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project), together with any additional information or analysis developed during a Remedial Investigation.	**4.0 BASIS FOR PROJECTED WASTE STREAMS AND VOLUMES AND POTENTIAL UNCERTAINTIES** This is a stand-alone section because of the added information since the PER. Because the RI and FS are presented together, there is no need to summarize the information.
1.4 FEDERAL, STATE, AND LOCAL ARARS AND TBCs This Section shall identify existing Federal, State, and Local ARARs and TBCs and consist of a detailed list of ARARs and TBCs based on information in Section 4.3 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation projects (See Outline A-1 in Appendix A to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project), together with any additional information, refinement, or analysis developed during the Remedial Investigation.	**7.2 CHEMICAL- AND LOCATION-SPECIFIC ARARS/TBCS** **8.2 SUMMARY OF ACTION-SPECIFIC ARARS/TBCS FOR EACH ALTERNATIVE** The ARARs are presented in two sections where they naturally fall in the process. The chemical and location-specific ARARs are presented at the beginning of Section 7 to support the development of RAOs. The action-specific ARARs are presented in Section 8.2, as required in Outline G-1, after the alternatives are developed.
1.5 PREMINARY REMEDIATION GOALS This Section should consist of information in Section 4.1 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation projects (See Outline A-1 in Appendix A to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion	This section is not needed. Because no environmental remediation is considered as part of this decision, decision-specific PRGs have not been developed. PRGs are contaminant-specific levels that help in an initial assessment of remediation alternatives.

Crosswalk between the DFF&O FS Outline and the RI/FS Report Sitewide Waste Disposition Evaluation Project (Continued)

DFF&O Requirements for the FS (Outline G-1)	Equivalent Contents of the RI/FS Report
Plant (Decontamination and Decommissioning (D&D) Project), together with any additional information, refinement, or analysis developed during a Remedial Investigation.	
2.0 PRELIMINARY IDENTIFICATION AND SCREENING OF WASTE DISPOSITION ALTERNATIVES	**7.0 PRELIMINARY IDENTIFICATION AND SCREENING OF WASTE DISPOSITION ALTERNATIVES**
2.1 INTRODUCTION	**7.1 INTRODUCTION**
2.2 REMEDIAL ACTION OBJECTIVES This Section should consist of information in Section 4.1.3 of the Remedial Investigation Report for the Site-Wide Waste Disposition Evaluation project (See Outline E-1 in Appendix E to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project), together with any additional information, refinement or analysis developed during a Remedial Investigation.	**7.3 RAOS**
2.3 INITIAL IDENTIFICATION AND PRELIMINARY SCREENING OF WASTE DISPOSITION ALTERNATIVES (*includes AAD*) This Section is based on the Alternative Array Document described in Section 7.2 of the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies)for the Portsmouth Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project. The AAD should be attached as an appendix to a Feasibility Study Report. This Section should also take into account information in Sections 4.4, 4.4.1, 4.4.2, and 4.4.3 of the Preliminary Evaluation Report (PER) for the Site-Wide Waste Disposition Evaluation project (See Outline A-1 in Appendix A to the Generic Statement of Work for Remedial Investigation(s)/Feasibility Study(ies) for the Portsmouth U.S. Gaseous Diffusion Plant (Decontamination and Decommissioning (D&D) Project), together with any additional information or analysis developed during a Remedial Investigation.	**7.4 INITIAL IDENTIFICATION AND PRELIMINARY SCREENING OF WASTE DISPOSITION ALTERNATIVES [*includes AAD*]** The AAD is presented as part of the FS. The AAD contains the technology screening, development of alternatives, and screening of alternatives. Because so few alternatives are under consideration, a step for development and screening of alternatives was not needed. Therefore, the AAD contains only a technology screening step and is therefore included in the FS directly instead of being submitted separately. The development and description of alternatives are presented in Section 8.
2.4 DRAFT WAC This Section will include a draft WAC if an alternative being considered includes a potential OSDC.	**7.5 WAC FOR REPRESENTATIVE WASTE DISPOSAL FACILITIES** Because there were four representative disposal process options, WAC for all four options are included in this section, and it was retitled to be more descriptive. The

Crosswalk between the DFF&O FS Outline and the RI/FS Report Sitewide Waste Disposition Evaluation Project (Continued)

DFF&O Requirements for the FS (Outline G-1)	Equivalent Contents of the RI/FS Report
	draft numerical WAC for a potential OSDC cannot be developed until the conceptual design of the cell is complete, Section 8. Therefore, Section 7.5 presents the approach for calculating WAC and Section 8 contains the results of the calculations.
3.0 FINAL DEVELOPMENT OF ALTERNATIVES	**8.0 FINAL DEVELOPMENT OF ALTERNATIVES**
3.1 DEVELOPMENT OF ALTERNATIVES TO BE PRESENTED IN PROPOSED PLAN AND RECORD OF DECISION	**8.1 DEVELOPMENT OF ALTERNATIVES** The title has been modified slightly although the content is the same as anticipated in the Outline.
3.2 SUMMARY OF ACTION-SPECIFIC ARARS FOR EACH ALTERNATIVE	**8.2 SUMMARY OF ACTION-SPECIFIC ARARS/TBCS FOR EACH ALTERNATIVE**
3.3 DETAILED DESCRIPTION OF ALTERNATIVES	**8.3 DETAILED DESCRIPTION OF ALTERNATIVES**
4.0 DETAILED ANALYSIS OF ALTERNATIVES	**9.0 DETAILED ANALYSIS OF ALTERNATIVES**
4.1 CRITERIA FOR ANALYSIS The nine CERCA evaluation criteria will be used to evaluate the remedial alternatives carried forward into the detailed analysis.	**9.1 CRITERIA FOR ANALYSIS**
4.2 INDIVIDUAL ANALYSIS OF ALTERNATIVES	**9.2 INDIVIDUAL ANALYSIS OF ALTERNATIVES** CERCLA criteria, NEPA values, as well as irreversible and irretrievable commitment of resources are evaluated.
4.3 COMPARATIVE ANALYSIS OF ALTERNATIVES	**9.3 COMPARATIVE ANALYSIS OF ALTERNATIVES**
5.0 ATTACHMENTS	**APPENDIX F: ARARs** **APPENDIX G: ENGINEERING STUDY OF PROCESS BUILDING EQUIPMENT SUBSIDENCE AVOIDANCE PROCESS OPTIONS** **APPENDIX H: FILL SOURCE EVALUATION FOR THE ON-SITE DISPOSAL COMPONENT OF ALTERNATIVE 2, THE COMBINED ON-SITE AND OFF-SITE DISPOSAL ALTERNATIVE** **APPENDIX I: DRAFT PERFORMANCE-BASED ACTIVITY AND CHEMICAL CONCENTRATION WASTE ACCEPTANCE DEVELOPMENT CRITERIA**

Crosswalk between the DFF&O FS Outline and the RI/FS Report Sitewide Waste Disposition Evaluation Project (Continued)

DFF&O Requirements for the FS (Outline G-1)	Equivalent Contents of the RI/FS Report
5.0 ATTACHMENTS (continued)	**APPENDIX J: ON-SITE DISPOSAL CELL CONCEPTUAL DESIGN FOR SITE D (ALTERNATIVE 2)** **APPENDIX K: METHODS AND RESULTS TO SUPPPORT INDIVIDUAL ANALYSES OF ALTERNATIVES** **APPENDIX L: COST ESTIMATE**

Crosswalk between the Generic Statement of Work for Conducting Remedial Investigation(s) and Feasibility Study(ies) and the Sitewide Waste Disposition Evaluation Project RI/FS Report

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
1.0 Purpose	
This Generic Statement of Work (SOW) for Conducting Remedial Investigations and Feasibility Studies sets forth the generic requirements for initiating, conducting and documenting Remedial Investigations and Feasibility Studies (RI/FS) for the Site-Wide Waste Disposition Evaluation project, and the Process Buildings and the Complex Facilities Decontamination and Decommissioning (D&D) Evaluation projects listed in Attachment H to these Orders, at the Department of Energy (DOE) Portsmouth Site.	NA
The purpose of an RI is to determine the threat to human health, safety and the environment in relation to project activities at the Site. The RI process emphasizes appropriate data collection and Site characterization, and is generally performed concurrently and in an interactive fashion with the feasibility study process. The RI process includes sampling and monitoring, as necessary, and includes gathering of sufficient information to determine the necessity for remedial action and to support the evaluation of remedial alternatives for each Remedial Action project at the Site. The purpose of a FS is to develop and evaluate options for remedial action(s) to reduce or eliminate the threat to human health, safety and the environment. The Respondent shall gather enough information to develop and evaluate remedial alternatives to provide the Ohio Environmental Protection Agency (Ohio EPA) with the information needed to concur or approve, as applicable, with a remedy(ies). The RI and FS are conducted simultaneously and in an interactive manner to allow the information gathered during the RI to influence the development of remedial alternatives, which in turn affects data needs and the scope of the RI.	All
The RI/FS shall be performed in accordance with the requirements of the consensual Director’s Final Findings and Orders for the Site, referred to herein as “Orders”, and this SOW, and in a manner consistent with the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), Final Rule (40 CFR Part 300). Respondent shall refer to appropriate sections of U.S. EPA’s Guidance for Conducting Remedial Investigations and Feasibility Studies under CERCLA (EPA/540/G-89/004, October 1988) (U.S. EPA RI/FS Guidance) and other guidance that the Ohio EPA may use in conducting an RI/FS. A list of documents is provided as Attachment C to the Orders to provide direction and guidance for conducting investigations and developing and evaluating remedial action alternatives. The applicability of individual guidance will be determined by the scope of the response action and data needs as determined during the scoping phase. Sections of relevant guidance which further describe the RI/FS tasks are referenced throughout this SOW and appendices. Ohio EPA and/or Respondent may identify other relevant guidance to be used in connection with performance of the RI/FS as Work proceeds under the Orders. Respondent shall furnish all personnel, materials, and services needed or incidental to performing the RI/FS except as otherwise specified in the Orders.	NA

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	**RI/FS Report Section**
At the completion of a RI/FS for each Remedial Action project, the Respondent shall be responsible for the selection of a remedy and shall memorialize the selected remedy in a Record of Decision (ROD) for each Remedial Action project. The remedy selected by the Respondent shall be protective of human health and the environment, comply with applicable or relevant and appropriate requirements (ARARs) of federal and state environmental laws and regulations or satisfy the requirements of 42 U.S.C. Section 9621 and 40 CFR Section 300.430 pertaining to waiver or non-attainment of ARARs, be cost-effective, utilize permanent solutions and treatment technologies or resource recovery technologies to the maximum extent practicable, and address the preference for treatment as a principal element. The final RI and FS Reports for each Remedial Action project, as concurred with or approved, as applicable, by Ohio EPA, shall, with the administrative record, form the basis for selection of the remedy(ies) and provide the information needed to support development of the ROD(s).	All
Ohio EPA shall provide oversight of Respondent's activities throughout the RI/FS for each Remedial Action project, including field activities. Respondent shall support Ohio EPA's conduct of oversight activities.	NA
2.0 RI/FS Scoping	Completed
Scoping is the planning process for the RI/FS. Consistent with the Orders and preliminary Site-specific Objectives (SSOs), and in consultation with Ohio EPA, Respondent shall determine the specific project scope and prepare and submit for review and comment a Pre-investigation Evaluation Report (PER) for each Remedial Action project.	
2.1 Project Initiation Meeting (PIM) and Site Visit	Completed
2.2 Pre-investigation Evaluation Report (PER)	Completed
2.3 PER Elements	Completed
3.0 RI/FS Work Plan and Supporting Documents	
3.1 RI/FS Work Plan (U.S. EPA RI/FS Guidance Section 2.3.1) (SOW Appendix B, outlines B-1 and B-2)	Completed
3.2 Sampling Plan (SOW Appendix C, outlines C-1 and C-2)	Completed
3.3 Quality Assurance Project Plan (SOW Appendix D)	Completed
3.4 Health and Safety Plan (U.S. EPA RI/FS Guidance Section 2.3.3)	Completed

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
3.5 Waste/Contaminant or Site Characterization (SOW Appendix B, outlines B-1 and B-2)	Section 2
Consistent with the applicable outline in Appendix B of this SOW, Respondent shall conduct such investigations as are necessary to obtain data of sufficient quality and quantity to support each RI/FS and identification and evaluation of potential remedial action alternatives. Geophysical characterization methods, such as ground penetrating radar, magnetometry, tomography, or other electromagnetic methods shall be used as appropriate to gather data necessary to support the tasks associated with the RI/FS for the Site-Wide Waste Disposition Evaluation project and the Process Buildings and Complex Facilities D&D Evaluation projects. All sampling, analyses, and measurements shall be conducted in accordance with the concurred upon or approved, as applicable, QAPP and SP. All sampling and measurement locations shall be documented in a project-specific field log and identified on project maps. Respondent shall document the procedures used in making the above determinations. The following sections describe the characterization elements for the Site-Wide Waste Disposition Evaluation project and the Process Buildings and Complex Facilities D&D Evaluation projects.	
3.5.1 Site-Wide Waste Disposition Evaluation Project (SOW Appendix B, Section 1.0 of outline B-1) Consistent with Outline B-1 in Appendix B to this SOW, Respondent shall collect the following data:	
I. Anticipated Waste Streams A. Waste anticipated to be generated during performance of Work under the Orders	Section 2.2.1 and 4
B. Potential waste streams associated with environmental media cleanup activities to be conducted under the RCRA Consent Decree and for which DOE might seek exemptions under Ohio laws and regulations to allow placement of such waste streams in any OSDC that might be constructed as a result of the Site-Wide Waste Disposition Evaluation project. Information to be included with respect to I.A. and I.B., above, should include: a. Nature of anticipated waste streams (e.g., radioactive, mixed waste, hazardous waste, solid waste, radioactive TSCA, non-radioactive TSCA, etc.); b. Estimated quantity or volume, including basis for estimate; and c. Anticipated types of waste within each of the general waste stream categories (e.g., liquid, solid, rubble, equipment, etc.)	Section 4
3.5.2 Process Buildings and Complex Facilities D&D Evaluation Projects (SOW Appendix B, Section 1.0 of outline B-2)	NA
4.0 Environmental Setting The requirement to address the Environmental Setting shall only apply to the Site-Wide Waste Disposition Evaluation project and will only be required if an OSDC is anticipated to be evaluated as one of the remedial alternatives for that project. Consistent with Outline B-1 to Appendix B of this SOW, Respondent shall collect information to supplement and verify existing information on the environmental setting of the Site and surrounding the Site. Characterization of the environmental setting shall, as relevant and appropriate, include but not be limited to, regional hydrogeology, hydrogeology, subsurface soil and rock units, surface soils, surface water and sediment, land use, land cover, local climate and human and ecological receptors. Components to be addressed may include:	Section 3

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	**RI/FS Report Section**
I. Regional Hydrogeology Respondent shall describe the regional hydrogeology surround the Site, including:	Sections 3.4, 3.6, & Appendix D
A. Depth to bedrock;	Section 3.4, Appendix D
B. Hydrostratigraphic unit correlation (both map and profile view);	Section 3.6, Appendix D
C. Aquifer and aquitard delineation;	Section 3.6, Appendix D
D. Active and inactive residential, public, industrial, agricultural, and other production well locations within a four (4) mile radius of the Site;	Section 3.6, Appendix D
E. Well logs, with well construction details and average yield;	Appendix B
F. Average pumping rates for production wells;	Section 3.6
G. Ambient ground water quality characterization;	Section 3.6
H. Average depth to water;	Section 3.6
I. Seasonal variation in ground water flow direction;	Section 3.6
J. Recharge and discharge area identification;	Section 3.6
K. Source water protection area identification;	NA
L. Aquifer designation (e.g., federal Sole Source Aquifer; Drinking Water Source Water Protection Area);	Appendix D
M. Regional geomorphology and topography, including locations of surface water bodies and floodways. This description should include an analysis of any features that may influence the ground water flow system; and	Sections 3.1, 3.6, & Appendix D
N. Structural feature delineation, including bedding planes and fold, joint, and fracture trace orientation.	Section 3.4
II. Site Hydrogeology Respondent shall characterize hydrogeology for candidate locations for a potential OSDC based on data collected from bore holes, monitoring wells, piezometers, and laboratory and field tests. As appropriate, characterization shall include:	
A. An accurate classification and description of the consolidated and unconsolidated stratigraphic units beneath the Site, including: 1. Hydraulic conductivity (vertical and horizontal); 2. Porosity, effective porosity, and bulk density; 3. Rock and soil (ASTM 2488 and 2487) classification; 4. Grain size distribution (sieve and hydrometer) curves; 5. Moisture content; 6. The attenuation capacity and mechanisms of attenuation of the natural earth material and/or fill (i.e., ion exchange capacity, base saturation, organic carbon content, mineral content, soil sorptive capacity, storage capacity); and 7. pH;	Sections 3.4, 3.6, & Appendix D
B. Surface soils, including: 1. Soil Conservation Service soil classification; 2. Surface soil distribution; 3. Depth and profile; 4. Organic carbon; 5. pH; 6. Porosity (total, air-filled); 7. Bulk density; 8. Gravimetric soil moisture content; 9. Fraction of vegetative cover (of contaminated areas); 10. Ion exchange capacity; 11. Infiltration; and 12. Evapotranspiration	Section 3.5, Appendix D

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
C. A description of the local ground water flow regime, including:	
1. Identification of all aquitards and aquifer systems (hydrogeologic formations wholly or partially saturated and capable of transmitting flow);	Section 3.6
2. Identification of saturated zones;	Section 3.6
3. Identification of water table and potentiometric surface depth with degree of seasonal fluctuation;	Section 3.6
4. Identification of seasonal ground water flow direction for each aquifer system including water table and/or potentiometric surface contour maps for each significant zone of saturation;	Section 3.6, Appendix D
5. Quantification of flow rate throughout each aquifer system;	Section 3.6
6. Quantification of horizontal and vertical gradients;	Section 3.6, Appendix D
7. Quantification of infiltration rates through the unsaturated zone;	Section 3.6, Appendix D
8. Quantification of flow across and lateral to hydrostratigraphic units, including the degree of seepage and upward leakage;	Appendix I
9. Quantification of flow budget across the Site with identification of recharge and discharge areas;	Appendix I
10. Location of nearest hydraulic boundaries;	Section 3.6
11. Characterization of ambient ground water chemistry both upgradient and downgradient of the Site;	Section 2.1, Appendix D
12. Hydrostratigraphic cross sections depicting horizontal and lateral extent, depth, and thickness of units. Cross sections shall be developed both longitudinally and transverse to the dominant direction of flow across the Site. Cross sections shall include flow nets distinguishing vertical and horizontal components of flow across stratigraphic units; and	Section 3.6, Appendix D
13. Delineation of structural features, including orientation, density, and distribution.	Section 3.4
D. A description of man-made influences that may affect the hydrogeology of the Site, identifying:	
1. Active and inactive water supply and production wells with pumping schedules; and	NA
2. Man-made structures such as injection wells, pipelines, french drains, ditches, unlined and lined ponds, lagoons, septic tanks, NPDES permitted out falls, retention areas and utility lines.	Section 3.6
E. An area-specific description of the geomorphology. At a minimum this shall include:	
1. An analysis of any topographic feature that may influence the ground water flow system;	Section 3.3, Appendix D
2. A surface topography map depicting (at a minimum) streams, wetlands, topographic depressions and springs. The topographic map shall be constructed by a qualified professional and shall provide contour intervals at a level of detail appropriate for the Site-specific hydrogeologic investigation (e.g., two-foot intervals). The map shall depict the location of all borings, monitoring wells and cross sections.	Appendix D
F. The RI Report shall document the methods and procedures used to gather and evaluate the hyrogeologic data. These methods and procedures shall be in accordance with the RI/FS Work Plan concurred with or approved, as applicable, by Ohio EPA. Field methods may include but are not limited to: 1. Borehole characterization; 2. Ground water level measurements; 3. Ground water sampling; 4. Monitoring well and piezometer installation; 5. Aquifer testing (e.g., pump and slug testing) to determine the degree of hydraulic communication between hydrostratigraphic units and subsurface structure; 6. Remote sensing, including geophysical techniques to identify zones of saturation,	Section 2.2

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	**RI/FS Report Section**
hydrostratigraphic units, and subsurface structure;	
7. Ground water tracer testing to assist in determining migration pathways and hydraulic conductivity; and 8. Isotopic age dating of ground water to assist in migration identification.	
III. Surface Water and Sediment Respondent shall characterize relevant surface water bodies in the vicinity of the Site. As appropriate, such characterization shall include, but not be limited to:	
A. Description of the perennial and ephemeral surface water bodies including: 1. For lakes and estuaries: location, elevation, surface area, inflow, outflow, depth, temperature stratification and volume; 2. For impoundments: location, elevation, surface area, depth, volume, freeboard and purpose of impoundment; 3. For streams, ditches, drains, wetlands, and channels: location, hydraulic gradient, flow velocity, base flow, depth, width, bank height and slope, gaining and losing stream sections, seasonal fluctuations, stabilization of stream bed; description of stream banks; flood plain areas, and flood zones (i.e., 50 and 100 year events); area of drainage basin; 4. Drainage patterns/storm water runoff; 5. Degree of ground water seepage and/or recharge to surface water bodies; and 6. Any known discharges including those permitted by NPDES.	Section 3.3
B. Description of the chemical, physical and biological/biochemical characteristics of the surface water and sediments. This includes but is not limited to:	
1. Chemical (surface water and/or sediment) a) Total organic carbon (TOC); b) pH; c) Total dissolved solids; d) Total suspended solids; e) Biochemical oxygen demand (BOD); f) Conductivity; and g) Dissolved oxygen.	Section 3.3 Most NA
2. Physical (surface water and/or sediment) a) Temperature; b) Particle/grain size; c) Appearance/texture/odor/color; d) Organic matter deposition; e) Deposition area, patterns, and rates; and f) Thickness profile.	Section 3.3 Most NA
3. Biological/Biochemical a) Aquatic life use designation based on Ohio's Water Quality Standards2; b) Attainment status of water body; and c) Ohio wetland classification.	Sections 3.8.2, 3.8.3
4. The RI Report shall document the methods and procedures used to gather and evaluate the surface water and sediment data. These methods and procedures shall be in accordance with the RI/FS Work Plan concurred with or approved, as applicable, by Ohio EPA. Field methods may include but are not limited to: a) Drain tracer studies; b) Seepage meter installation and data acquisition; c) Stream piezometer installation and water level acquisition; and d) Stream weir gauge installation and data acquisition.	NA
IV. Local Climate Respondent shall provide relevant information characterizing the climate in the vicinity of the Site in general and at the time of the investigation(s). As appropriate, such information shall include, but not be limited to:	

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
A. Description of the following parameters: 1. Annual and monthly rainfall averages; 2. Monthly temperature averages and extremes; 3. Wind speed and direction; 4. Relative humidity/dew point; 5. Atmospheric pressure; 6. Evaporation data; 7. Development of inversions; and 8. Climate extremes that have been known to occur in the vicinity of the Site, including frequency of occurrence.	Section 3.2
B. A description of topographic or manmade features which may affect air flow or emission patterns, including: 1. Ridges, hills or mountain areas; 2. Canyons or valleys; 3. Surface water bodies; 4. Wind breaks and forests; 5. Buildings; and 6. Any other features that may affect air flow or emission patterns.	NA
V. Human receptors potentially exposed to Site-related contaminants: A. Human population data including demographics; B. Sensitive sub-populations; C. Populations served by surface water intakes or ground water wells; and D. Land use (e.g., residential, commercial, recreational).	Sections 3.7, 5.1
VI. Ecological receptors potentially exposed to Site-related contaminants, including: A. Terrestrial receptors; B. Aquatic receptors; and C. Special interest species (including Threatened and Endangered species).	Sections 3.8, 5.2
5.0 Threat to Human Health, Safety and the Environment (SOW Appendix E, Section 4.0 of outlines E-1 and E-2) Respondent shall prepare reports for the Site-Wide Waste Disposition Evaluation project and the Process Buildings and Complex Facilities D&D Evaluation projects consistent with the applicable outlines that appear as appendices to this SOW. Data collected for each Remedial Action project shall be sufficient to support a streamlined evaluation of threats to human health, safety and the environment as required by the applicable appendices to this SOW. Respondent shall collect any necessary data in accordance with a RI/FS Work Plan concurred with or approved, as applicable, by Ohio EPA and shall document the methods and procedures used during the investigation in each RI Report. Section 3.5 of this SOW summarizes the requirements for Waste/Contaminant and Site Characterization data that will be used in the streamlined evaluation.	
5.1 Site-Wide Waste Disposition Evaluation Project (SOW Appendices A and E, Sections 3.3 and 3.4 of outline A-1 and Section 4.0 of outline E-1) Respondent shall prepare a streamlined evaluation of the types of hazards typically associated with the anticipated waste streams sufficient to support evaluation of potential alternatives for Site-wide waste disposition. The streamlined risk evaluation shall utilize the data collected and assembled in accordance with Section 3.5 of this SOW. The streamlined risk evaluation shall discuss potential on-Site receptors (workers) and off-Site receptors (plant neighbors and other members of the public that might directly contact waste streams from the Site during and after on-Site disposal, and during off-Site transportation of waste), and environmental receptors.	Sections 5, 9.2.2.1.5, & 9.2.3.1.5
5.2 Process Buildings and Complex Facilities D&D Evaluation Projects (SOW Appendices A and E, Sections 3.3 and 3.4 of outline A-2 and Section 4.0 of outline E-2)	NA

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
6.0 Remedial Investigation Report (SOW Appendix E, outlines E-1 and E-2) Respondent shall submit for Ohio EPA review and concurrence or approval, as applicable, RI Reports for each Remedial Action project detailing the methods and results of the remedial investigations and the potential threats to human health, safety and the environment. The sample outlines for the RI Reports are provided in Appendix E of this SOW.	Sections 2 - 6
7.0 Developing and Screening of Remedial Alternatives (U.S. EPA RI/FS Guidance Chapter 4) (SOW Appendix G, Section 2.0 of outlines G-1 and G-2) Consistent with the applicable outline in Appendix G of this SOW, Respondent shall develop and screen remedial alternatives to arrive at an appropriate range of alternatives for detailed analysis for the Site-Wide Waste Disposition Evaluation project and the Process Buildings and Complex Facilities D&D Evaluation projects. The following activities are to be performed by Respondent as needed during the development and screening of remedial alternatives.	
7.1 Refine Remedial Action Objectives (U.S. EPA RI/FS Guidance Section 4.2.1) (SOW Appendix G, Section 2.2 of outlines G-1 and G-2) Consistent with the applicable outline in Appendix G of this SOW, Respondent shall further refine the RAOs identified during project scoping. The refined RAOs for each Remedial Action project shall be based on the results of the RI and, in the case of the Site-Wide Waste Disposition Evaluation project, and then Ohio EPA-approved WAC if an OSDC is evaluated as a possible remedial alternative. The RAOs also shall be consistent with Section 300.430 of the NCP. Respondent shall prepare and submit for review an Interim Technical Memorandum (ITM) identifying the refined RAOs for protection of human health and the environment and detailing the methods and procedures used to refine them. The refined RAOs shall be included in the Alternatives Array Document described below.	Section 7.3
7.2 Alternatives Array Document (U.S. EPA RI/FS Guidance Chapter 4) (SOW Appendix G, Section 2.3 of outlines G-1 and G-2) Consistent with the applicable outline in Appendix G of this SOW, Respondent shall prepare an Alternatives Array Document (AAD) for each Remedial Action project which documents the methods, rationale, and results of the alternatives development and the screening process. Respondent shall include an evaluation of whether the amount and type of data existing for each Remedial Action project at the Site will support the subsequent detailed analysis of the alternatives. Respondent shall assure identification of an appropriate range of viable alternatives for consideration in the detailed analysis. The final AAD shall be combined with the detailed analysis of alternatives to form the FS Report described in Section 8 and Appendix G of this SOW. The following sections summarize the requirements for conducting the alternatives screening process and provide the required contents of the AAD as it pertains to the Site-Wide Waste Disposition Evaluation project and the Process Buildings and Complex Facilities D&D Evaluation projects.	Sections 7 and 8

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	**RI/FS Report Section**
I. Technologies Screening (Section 4.2.2 through 4.2.5.3 of the U.S. EPA RI/FS Guidance) A. Develop General Response Actions (U.S. EPA RI/FS Guidance 4.2.2) Respondent shall refine the general response actions initially identified during project scoping. General response actions shall be identified describing actions, singly or in combination, to satisfy the RAOs. B. Identify anticipated waste/contaminant streams for each Remedial Action project area at the Site and, for the Site-Wide Waste Disposition Evaluation Project only, establish preliminary criteria for waste/contaminant acceptance if an OSDC is anticipated to be evaluated as a possible remedial alternative under the Site-Wide Waste Disposition Evaluation Project. (U.S. EPA RI/FS Guidance 4.2.3). Respondent shall identify areas or volumes of waste/contaminants to which general response actions may apply, taking into account requirements for protectiveness as identified in the RAOs, Site conditions, and the nature and extent of contamination (Section 4.2.3 of the U.S. EPA RI/FS Guidance). C. Identify, Screen, and Document Remedial Technologies (U.S. EPA RI/FS Guidance 4.2.4) Respondent shall identify, screen and evaluate remedial technologies applicable to each general response action to eliminate those that cannot be technically implemented based on contaminant types and concentrations and/or Site characteristics. Decisions made during the remedial technology screening shall be documented for inclusion in the Alternatives Array Document.	Section 7.4
D. Evaluate and Document Process Options (U.S. EPA RI/FS Guidance 4.2.5) As appropriate, process options for each surviving technology type shall be identified and evaluated on the basis of effectiveness, implementability, and cost as those criteria are defined in Section 4.2.5 of the U.S. EPA RI/FS Guidance. Respondent shall select and retain, wherever appropriate and possible, one or more representative process options for each implementable technology type. The evaluation should focus on effectiveness factors at this stage with less effort directed as the implementability and cost factors. Identifying and screening process options shall be documented for inclusion in the Alternatives Array Document. Respondent shall consider the NCP's preference for treatment over conventional containment or land disposal approaches.	Section 7.4
II. Alternatives Array Document (U.S. EPA RI/FS Guidance 4.2.6) Respondent shall submit for review and comment an AAD for each Remedial Action project consisting of the following:	
A. Assemble and Document Alternatives Respondent shall assemble the selected representative technologies into remedial alternatives. Each alternative should comprehensively address the Site-specific PRGs, RAOs, and ARARs. Each alternative shall describe the locations of the Site affected; approximate volumes of any wastes/contaminants to be removed or treated; and any other information needed to adequately describe the alternative and document the logic behind each specific remedial alternative.	Section 8.1

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	**RI/FS Report Section**
B. Conduct and Document the Screening Evaluation of Each Alternative Respondent may perform, or Ohio EPA may require, that the assembled alternatives undergo a screening process based on short and long term aspects of effectiveness, implementability, and relative cost as those criteria are defined in Section 4.3 of the U.S. EPA RI/FS Guidance. Screening of the alternatives is generally performed when there are many feasible alternatives available for detailed analysis. The screening may be conducted to assure that only those alternatives with the most favorable composite evaluation of all factors are retained for further analysis, while at the same time preserving an appropriate range of remedial options. Prior to conducting a screening of alternatives, Respondent shall further define the alternatives such that design considerations for technologies and the ability of the alternatives to satisfy the RAOs are described. The purpose shall be to ensure that a basis exists for evaluating and comparing the alternatives before proceeding with the alternative screening step (Section 4.3.1 of the U.S. EPA RI/FS Guidance). Respondent shall prepare a summary of the assembled remedial alternatives and their related ARARs, specifically including an analysis of how siting criteria contained in Ohio Administrative Code (OAC) Chapters 3745-27 and 3745-50 will be met and provide the reasoning employed in the alternative screening. The alternatives summary shall be submitted with the AAD.	NA
III. Post-screening Considerations At the conclusion of the alternative screening phase, or if no screening is needed, Respondent shall determine if the amount and type of data existing for the Remedial Action project area will support the detailed analysis of the surviving remedial alternatives (Section 4.3.3.3 of the U.S. EPA RI/FS Guidance). Specifically, Respondent shall consider whether any additional field investigation or treatability testing is necessary prior to proceeding with the detailed analysis of alternatives. If Respondent determines that additional data or treatability testing is needed, Respondent shall document the determination, the specific types of data needed; and the time frame for obtaining the data in the AAD. If Ohio EPA concurs with or approves, as applicable, Respondent's determinations, Respondent shall, in accordance with the Orders, submit for review and concurrence or approval, as applicable, an addendum to the RI/FS Work Plan and supporting documents and/or a treatability study work plan for obtaining the additional data. Should Ohio EPA determine, based on review of the AAD, that additional data is needed to perform the detailed analysis of alternatives, Ohio EPA shall notify Respondent of the need for additional data, and Respondent may either submit for review and concurrence or approval, as applicable, an addendum to the RI/FS Work Plan and supporting documents and/or a Treatability Study Work Plan to obtain the additional data or dispute the Ohio EPA determination pursuant to the provisions of the Orders.	NA

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
Respondent shall begin to develop and evaluate a range of remedial alternatives during RI/FS scoping (Section 1.0 and Appendix A of this SOW; Section 2.2.3 of the U.S. EPA RI/FS Guidance). Respondent shall continue to develop and evaluate the remedial alternatives initially developed during project scoping as RI data become available. With the exception of the "no action" alternative, all alternatives under consideration must, at a minimum, ensure protection of human health and the environment and comply with the applicable or relevant and appropriate requirements of state and federal laws and regulations or satisfy the requirements of 42 U.S.C. Section 9621 and 40 CFR Section 300.430 pertaining to waiver or non-attainment of ARARs. Consistent with Section VI (Performance of the Work By Respondent) of the Orders, if an OSDC is evaluated as a possible remedial alternative under the Site-Wide Waste Disposition Evaluation project, Respondent shall evaluate at least one alternative or sub-alternative that is fully ARARs compliant, with no ARARs waived.	Section 8.1
8.0 Treatability Studies (SOW Appendix F outlines F-1 and F-2)	NA
9.0 Feasibility Study Report (U.S. EPA RI/FS Guidance Section 5.5); (SOW Appendix G, outlines G-1 and G-2) Once Ohio EPA and Respondent have determined that sufficient data exist to proceed, Respondent shall conduct a detailed analysis of the alternatives surviving the screening process to provide the information needed for selection of a remedy for each Remedial Action project area. If an alternative providing for an OSDC is carried forward for detailed analysis, the FS Report shall include a draft WAC. The detailed analysis shall consist of an individual analysis of each alternative against the nine CERCLA evaluation criteria followed by a comparative analysis of the alternatives using the same evaluation criteria as the basis for comparison. Respondent shall prepare and submit an FS Report for each Remedial Action project for review and concurrence or approval, as applicable. The final AAD shall be incorporated into the FS (SOW Appendix G, Section 2.3 of outlines G-1 and G-2). In addition, Respondent will refer to Appendix G of this SOW for an outline of the FS Report format and required report content. The detailed analysis of remedial alternatives shall consist of the following elements:	Sections 7 - 9
I. Detailed Description of Each Alternative (U.S. EPA RI/FS Guidance Sections 6.2.1 to 6.2.4) The detailed narrative description of each alternative shall include at a minimum:	
A. Description of each technology component;	Sections 8.3.2 and 8.3.3
B. Refinement of the volumes and/or areas of contaminated media to be addressed;	Section 4
C. Special engineering considerations required to implement the alternative, (e.g., pilot treatment facility or additional studies needed to proceed with final remedial design);	Section 8.3.2.1.2
D. Operation, maintenance and monitoring requirements, including the WAC (WAC requirement would only be applicable if an alternative including consideration of an OSDC was included under the Site-Wide Waste Disposition Evaluation project);	Sections 8.3.2.1.4 and 8.3.2.1.5
E. Temporary storage requirements;	Sections 8.3.2.1.1 and 8.3.2.1.5
F. Health and safety requirements related to implementation and operation and maintenance of the alternative, including on- and off-Site worker and general public health and safety considerations;	Section 8.3.2.1.5
G. An analysis of how the alternative could be phased into individual operations and a discussion of how these operations could best be implemented to produce significant environmental improvement;	Section 8.3.2.1.3

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
H. A review of any off-Site treatment or disposal facilities and transportation needs to ensure compliance with the Resource Conservation and Recovery Act, TSCA, and state requirements; and	Sections 8.3.2.1.9 and 8.3.3
I. An analysis of the projected performance and expected results of the alternative with emphasis on potential for further future release of hazardous substances.	Sections 9.2.2.1.1 and 9.2.3.1.1
II. National Environmental Policy Act (NEPA) Considerations Respondent shall incorporate NEPA considerations into the CERCLA process as appropriate during evaluation of the remedial action alternatives.	Sections 9.2 and 9.3
III. Apply the Nine CERCLA Evaluation Criteria and Document the Individual Alternative Analysis Respondent shall apply the nine evaluation criteria described below to each individual alternative. Respondent shall document the decision making process and the results of the individual analysis of alternatives.	Section 9.2 and 9.3
A. Overall Protection of Human Health, Safety and the Environment. Respondent shall assess the alternatives to determine if they can adequately protect human health, safety and the environment from unacceptable risks posed by hazardous substances, pollutants or contaminants present at the project area by eliminating, reducing or controlling exposures to levels established during development of remediation goals. This is a threshold requirement and the primary objective of the remediation program.	Sections 9.2.1.1.1, 9.2.2.1.1, and 9.2.3.1.1
B. Compliance with Applicable or Relevant and Appropriate Requirements. Respondent shall assess the alternatives to determine if they attain applicable or relevant and appropriate standards, criteria and requirements of federal, state, and local laws or satisfy the criteria for ARARs waiver(s) or non-attainment as set forth in 42 U.S.C. Section 9621 and 40 CFR Section 300.430. This is also a threshold requirement. Consistent with Section VI (Performance of the Work by Respondent) of the Orders, if an OSDC is evaluated as a possible remedial alternative under the Site-Wide Waste Disposition Evaluation project, Respondent shall evaluate at least one alternative or sub-alternative that is fully ARARs compliant, with no ARARs waived.	Sections 9.2.1.1.2, 9.2.2.1.2, and 9.2.3.1.2
C. Long-term Effectiveness and Permanence. Respondent shall assess the alternatives for the long-term effectiveness and permanence they afford, along with the degree of certainty that the alternative will prove successful. Factors that shall be considered, if appropriate and/or applicable to an alternative, include the following: 1. Nature and magnitude of residual risk; potential for exposure of human and environmental receptors; concentrations of hazardous substances, pollutants or contaminant remaining after implementing the remedial alternative, considering the persistence, toxicity, mobility and propensity to bio-accumulate such hazardous substances and their constituents (see Risk Assessment Guidance for Superfund (RAGS), Part C); 2. The type, degree and adequacy of long-term management required for untreated substances and treatment residuals, including engineering controls (such as containment technologies), institutional controls, monitoring and operation and maintenance; 3. Long-term reliability of the engineering and institutional controls, including uncertainties associated with land disposal of untreated hazardous substances, pollutants, contaminants, and treatment residuals, and; 4. Potential need for replacement of the remedy, and the continuing need for repairs to maintain the performance of the remedy.	Sections 9.2.1.1.3, 9.2.2.1.3, and 9.2.3.1.3

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
D. Reduction of Toxicity, Mobility or Volume through Treatment Respondent shall assess the degree to which alternatives employ treatment that reduces toxicity, mobility or volume of contaminants. If Respondent determines that the NCP preference for such treatment is not appropriate and/or applicable to an alternative, Respondent shall provide an explanation for that determination. Where appropriate, Respondent shall identify alternatives which, at a minimum, address the principal threats posed by the Site through treatment. Factors that shall be considered, if appropriate and/or applicable to an alternative, include the following: 1. The treatment or recycling processes the alternatives employ and materials they will treat; 2. The amount of hazardous substances, pollutants or contaminants that will be destroyed, treated, or recycled; 3. The degree of expected reduction in toxicity, mobility, or volume of the waste/contaminants due to treatment or recycling and the specifications of which reduction(s) are occurring; 4. The degree to which the treatment is irreversible; 5. The type and quantity of residuals that will remain following treatment, considering the persistence, toxicity, mobility and propensity to bio-accumulate; 6. The degree to which treatment will reduce the inherent hazards posed by the principal threats at the Site; and 7. The degree to which the treatment processes employed will reduce the transfer of contaminants between environmental media.	Sections 9.2.1.1.4, 9.2.2.1.4, and 9.2.3.1.4
E. Short-term Effectiveness Respondent shall assess the short-term impacts of the alternatives during the construction and implementation phase, and until the objectives of a Remedial Action have been met. Factors that shall be considered, if appropriate and/or applicable, include the following: 1. Short-tem risks that may be posed to the community during construction and implementation of an alternative and until the RAOs have been met; 2. Potential impacts on workers during remedial action and until the objectives of remedial action have been met, the effectiveness and reliability of protective measures; 3. Potential environmental impacts that may result from the remedial action and the effectiveness and reliability of mitigative measures during implementation and until the objectives of the remedial action have been met; and 4. Time until response action objectives are achieved	Sections 9.2.1.1.5, 9.2.2.1.5, and 9.2.3.1.5
F. Implementability Respondent shall assess the technical and administrative feasibility of implementing the alternatives. Factors that shall be considered, if appropriate and/or applicable, include the following: 1. Technical Feasibility: a) Degree of difficulty or uncertainty associated with construction and operation of the alternative; b) Expected operational reliability of the alternative; c) Ease of undertaking additional remedial action(s); and d) Ability to monitor the effectiveness of the remedy.	Sections 9.2.1.1.6, 9.2.2.1.6, and 9.2.3.1.6

Generic SOW for Conducting Remedial Investigation(s)and Feasibility Study(ies)	RI/FS Report Section
2. Administrative Feasibility: Activities needed to coordinate implementation of the remedy with state, local, and federal agencies 3. Feasibility of Obtaining Services and Materials: a) Capacity and location of adequate treatment, storage, and disposal services; b) Availability of necessary equipment and specialists and provisions to ensure any necessary additional resources; c) Availability of services and materials; and d) Availability of prospective technologies.	
G. Cost The types of costs that shall be assessed, if appropriate and/or applicable, include the following: 1. Direct and indirect capital costs, including contingency and fees; 2. Annual operation and maintenance costs; and 3. Net present value of capital and O&M costs.	Sections 9.2.1.1.7, 9.2.2.1.7, and 9.2.3.1.7
H. Community Acceptance This criterion shall be addressed by Respondent throughout the conduct of each RI/FS and during the public comment period for each Proposed Plan and should include analysis of community input to identify which components of the alternatives local government and other interested persons in the community support, have reservations about, or oppose.	Section 9.1.1.9
I. State Acceptance Each FS Report should indicate that this criterion will be addressed in the Record of Decision following publication of the Proposed Plan and completion of the public comment period.	Section 9.1.1.8
IV. Compare Alternatives Against Each Other and Document the Comparison of Alternatives (U.S. EPA RI/FS Guidance Sections 6.2.5 and 6.2.6) At the conclusion of the individual analysis of alternatives, Respondent shall perform a comparative analysis between the alternatives. That is, each alternative will be compared against the others using the nine CERCLA evaluation criteria as a basis of comparison. Respondent shall document the decision making process and the results of the comparative analysis of alternatives for inclusion in the FS.	Section 9.3

AAD = Alternatives Array Document
ARAR = applicable or relevant and appropriate requirement
ASTM = American Society for Testing and Materials
CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act of 1980
CFR = Code of Federal Regulations
D&D = decontamination and decommissioning
ITM = Interim Technical Memorandum
NA = not applicable
NCP = National Oil and Hazardous Substances Pollution Contingency Plan
NEPA = National Environmental Policy Act of 1969
NPDES = National Pollutant Discharge Elimination System
O&M = operation and maintenance
OAC = Ohio Administrative Code
Ohio EPA = Environmental Protection Agency
OSDC = on-Site disposal cell
PRG = preliminary remediation goal
QAPP = Quality Assurance Project Plan
RI/FS = remedial investigation/feasibility study
RAO = remedial action objective
ROD = Record of Decision
SOW = statement of work
SP = sampling plan
TSCA = Toxic Substances Control Act of 1976
U.S. EPA = U.S. Environmental Protection Agency
WAC = waste acceptance criteria

APPENDIX A: ANALYTICAL SAMPLE RESULTS

This page is intentionally left blank.

Field log books, sample collection logs, and other appropriate quality assurance/quality control data related to analytical data in this appendix are maintained in the project records.

The following analytical data qualifiers were used for reporting analytical results (codes typically contained in the RSLTQUAL field):

Inorganic Analysis

B	This qualifier is used when the value was less than the Contract Required Detection Limit or Required Reporting Limit specified, but greater than or equal to the Instrument Detection Limit/Method Detection Limit
U	The analyte was analyzed for but not detected.
J	This qualifier indicates an estimated value.
E	The reported value is estimated because of the presence of interference. An explanatory note must be included under comments.
M	Duplicate injection precision was not met.
N	Spiked sample recovery was not within control limits.

Organic Analysis

U	Indicates compound was analyzed for but not detected.
J	This qualifier indicates an estimated value. It is used under the following circumstances: (1) when estimating a concentration for tentatively identified compounds where a 1:1 response is assumed and (2) when the mass spectral and retention time data indicate the presence of a compound that meets the pesticide/PCB identification criteria, and the result is less than the contract-required quantitation limit, but greater than zero.
B	This qualifier is used when the analyte is found in the associated blank as well as in the sample.
E	This qualifier identifies compounds whose concentrations exceed the calibration range of the gas chromatograph/mass spectrometer instrument for that specific analysis.
Y	This qualifier indicates matrix spike/matrix spike duplicate recovery and/or relative percent difference (RPD) failed to meet acceptance criteria.

Radionuclide Analysis

B	Method blank was not statistically different from sample at a 95 percent level of confidence.
U	Compound was analyzed for but not detected.
J	This qualifier indicates an estimated value.
X	Other specific qualifiers may be required to properly define the results.

D	Sample is statistically different from duplicate at a 95 percent level of confidence.
L	Expected and measured value for laboratory control sample is statistically different at a 95 percent level of confidence.
M	Expected and measured value for matrix spike is statistically different at a 95 percent level of confidence.

The following validation qualifiers were assigned by the data validators:

N	The analysis indicates the presence of an analyte for which there is presumptive evidence to make a tentative identification.
U	Analyte or compound was considered not detected above the reported detection limit.
J	Analyte or compound was identified; the associated numerical value is approximated.
UJ	Analyte or compound not detected above the reported detection limit, and the reported detection limit is approximated because of quality deficiency.
R	Result is not usable for its intended purpose, so data are of “information only” quality and should be supplemented with additional data for decision making.
XV	Data were not validated; refer to the RSLTQUAL field which may contain more information.
XZ	Data validation performed but no validation qualifier were applied; refer to the RSLTQUAL field which may contain more information.
=	Data were validated; however, no qualifier was added.
